ANSI/SCTE 35 2019r1

Digital Program Insertion Cueing Message for Cable

NOTICE

The Society of Cable Telecommunications Engineers (SCTE) / International Society of Broadband Experts (ISBE) Standards and Operational Practices (hereafter called "documents") are intended to serve the public interest by providing specifications, test methods and procedures that promote uniformity of product, interchangeability, best practices and ultimately the long-term reliability of broadband communications facilities. These documents shall not in any way preclude any member or non-member of SCTE•ISBE from manufacturing or selling products not conforming to such documents, nor shall the existence of such standards preclude their voluntary use by those other than SCTE•ISBE members.

SCTE•ISBE assumes no obligations or liability whatsoever to any party who may adopt the documents. Such adopting party assumes all risks associated with adoption of these documents, and accepts full responsibility for any damage and/or claims arising from the adoption of such documents.

Attention is called to the possibility that implementation of this document may require the use of subject matter covered by patent rights. By publication of this document, no position is taken with respect to the existence or validity of any patent rights in connection therewith. SCTE•ISBE shall not be responsible for identifying patents for which a license may be required or for conducting inquiries into the legal validity or scope of those patents that are brought to its attention.

Patent holders who believe that they hold patents which are essential to the implementation of this document have been requested to provide information about those patents and any related licensing terms and conditions. Any such declarations made before or after publication of this document are available on the SCTE•ISBE web site at http://www.scte.org.

1. Introduction

1.1. Executive Summary

This standard, "Digital Program Insertion Cueing Message for Cable" (SCTE 35), is the core signaling standard for advertising and distribution control (e.g., blackouts) of content for content providers and content distributors. SCTE 35 is being applied to QAM/IP, Title VI/TVE (TV Everywhere), and live/time shifted (DVR, VOD, etc.) delivery. SCTE 35 signals can be used to identify advertising breaks, advertising content, and programming content (e.g., specific Programs and Chapters within a Program).

SCTE 35 complements other Standards to complete the eco-systems. [SCTE 30] is used to support splicing of advertising into live QAM MPEG-2 transport streams. [SCTE 130-3] is used to support alternate content decisions (advertising, blackouts, stream switching) for live and time shifted delivery. [SCTE 214-1] defines how SCTE 35 is carried in MPEG-DASH. [SCTE 224] (ESNI) is used to pass event and policy information from provider or other systems to communicate distribution control instructions.

The recommended practices for SCTE 35 are contained in [SCTE 67] "Recommended Practice for Digital Program Insertion for Cable".

1.2. Scope

This standard supports delivery of events, frame accurate or non-frame accurate, and associated descriptive data in MPEG-2 transport streams, MPEG-DASH and HLS. This standard supports the splicing of content (MPEG-2 transport streams, MPEG-DASH, etc.) for the purpose of Digital Program Insertion, which includes advertisement insertion and insertion of other content types. This standard defines an in-stream messaging mechanism to signal splicing and insertion opportunities. As such, this standard does not specify the insertion method used or constraints applied to the content being inserted, nor does it address constraints placed on insertion devices.

Fully compliant MPEG-2 transport stream (either Multi Program Transport Stream or Single Program Transport Stream), MPEG-DASH content, etc. is assumed. No further constraints beyond the inclusion of the defined cueing messages are placed upon the stream.

This standard specifies a technique for carrying notification of upcoming points and other timing information in the transport stream. A splice information table is defined for notifying downstream devices of splice events, such as a network break or return from a network break. For MPEG-2 transport streams, the splice information table, which pertains to a given program, is carried in one or more MPEG Sections carried in PID(s) referred to by that program's Program Map Table (PMT). In this way, splice event notification can pass through most transport stream remultiplexers without need for special processing. For MPEG-DASH, the splice information table is carried in the DASH MPD (See [SCTE 214-1]) or in media segments (see [SCTE 214-2] and [SCTE 214-3]). Section 12.2 details how SCTE 35 messages are carried in HLS manifests.

1.3. Benefits

SCTE 35 is a key part of the eco-system to enable advertising and content distribution business. A common/well-formed signaling model enables downstream systems to be implemented in a cost effective, consistent and non-ambiguous fashion to achieve business objectives.

1.4. Intended Audience

The intended audience is Content Providers, Multi-Channel Video Program Distributors, TV Everywhere Providers/Distributors and vendors/developers who build solutions.

1.5. Areas for Further Investigation or to be Added in Future Versions

Follow-up work related to UHD and HDR *may* be addressed. The use of studio time is currently an active topic in the DASH-IF group and a future version of this standard *may* want to reference that work. Sections 10.3.3.5 to 10.3.3.11 *should* be reviewed.

2. Normative References

The following documents contain provisions, which, through reference in this text, constitute provisions of this document. At the time of Subcommittee approval, the editions indicated were valid. All documents are subject to revision; and while parties to any agreement based on this document are encouraged to investigate the possibility of applying the most recent editions of the documents listed below, they are reminded that newer editions of those documents might not be compatible with the referenced version.

2.1. SCTE References

5. Abbreviations and Definitions

5.1. Abbreviations

| ADI | Asset Distribution Interface |
|--------|--|
| Ad-ID | Advertisement Identifier |
| ATSC | Advanced Television Systems Committee. |
| bslbf | Bit string, left bit first, where left is the order in which bit strings are |
| | written. |
| DTMF | Dual tone multi frequency |
| DVB | Digital Video Broadcasting |
| FIPS | Federal Information Processing Standard |
| ISAN | International Standard Audiovisual Number (see [ISO 15706-1] and |
| | [ISO 15706-1 Amd 1]) |
| ISCI | Industry Standard Commercial Identifier |
| MPTS | a Multi Program Transport Stream. |
| MVPD | Multi-Channel Video Program Distributors; also cited as "content |
| | distributor", "distributor", or affiliate. |
| NTP | Network Time Protocol as defined in IETF [RFC5905]. |
| PID | Packet identifier; a unique 13-bit value used to identify the type of |
| | data stored in the packet payload (see [MPEG Systems]). |
| PMT | Program Map Table (see [MPEG Systems]). |
| PTP | Precision Time Protocol as defined in IEEE Std 1588-2008 PTP. |
| PTS | Presentation Time Stamp (see [MPEG Systems]). |
| rpchof | Remainder polynomial coefficients, highest order first. |
| SCTE | Society of Cable Telecommunications Engineers |
| SPTS | a Single Program Transport Stream. |

| STC | System Time Clock | |
|--------|--|--|
| TAI | International Atomic Time (TAI, from the French name Temps | |
| | Atomique International) This time reference scale was established by | |
| | the BIPM (Bureau International des Poids et Mesures) on the basis of | |
| | atomic clock readings from various laboratories around the world. | |
| TI | Turner Identifier | |
| TID | Tribune Identifier | |
| uimsbf | Unsigned integer, most significant bit first. | |
| UMID | Unique Material Identifier | |
| UPID | Unique Program Identifier | |
| URI | Uniform Resource Identifier—See [RFC 3986]. | |
| UTC | Coordinated Universal Time. This is the primary time standard by | |
| | which the world regulates clocks and time. | |
| V-ISAN | Version-ISAN (core ISAN number plus a version number) (see [ISO | |
| | 15706-2]). | |
| XML | Extensible Markup Language —See [W3C Recommendation, | |
| | "Extensible Markup Language (XML) 1.0] | |

5.2. Definitions

| Access Unit | A coded representation of a presentation unit (see [ITU H.262]). |
|----------------------------|--|
| Advertisement (also called | An inducement to buy or patronize. As used in the cable industry, |
| "ad") | usually with a duration under 2 minutes (sometimes called "short- |
| , | form" content). |
| Analog Cue Tone | In an analog system, a signal that is usually either a sequence of |
| | DTMF tones or a contact closure that denotes to ad insertion |
| | equipment that an advertisement avail is about to begin or end. |
| Avail | Time space provided to cable operators by cable programming |
| | services during a program for use by the MVPD operator; the time is |
| | usually sold to local advertisers or used for channel self-promotion. |
| Bit Stream Format | An encoding of information resulting in a compliant MPEG-2 |
| | transport stream. See [MPEG Systems]. |
| Break | Avail or an actual insertion in progress. |
| Chapter | A short section of a longer program, usually situated to permit a |
| | viewer to easily locate a scene or section of the program. |
| Component Splice Mode | A mode of the cueing message whereby the program_splice_flag is set |
| | to '0', indicating that each PID/component that is intended to be |
| | spliced will be listed separately by the syntax that follows. |
| | Components not listed in the message are not to be spliced. |
| Content | Generic term for television material, either advertisements or |
| | programs. |
| Content Distributor | Typically an MVPD; also cited as "distributor". |
| Content Provider | Typically a network programmer; also cited as "programmer" or |
| | "provider". |
| Cueing Message | See message. |
| Deprecated | Use is permissible for legacy purposes only. <i>Deprecated</i> features <i>may</i> |
| | be removed from future versions of the standard. Implementations |
| | should avoid use of deprecated features. |
| Event | A splice event or a viewing event. |

| A point in the stream, suitable for entry, that lies on an elementary | |
|--|--|
| presentation unit boundary. An In Point is actually between two | |
| presentation units rather than being a presentation unit itself. | |
| A device that receives the transport stream directly and is able to | |
| derive timing information directly from the transport stream. | |
| In the context of this document a message is the content of any | |
| splice info section. | |
| A transport stream with multiple programs. | |
| 11 transport out out in manager programmer | |
| A device that receives the cue message from an in stream device over | |
| a separate connection from the transport stream. An out of stream | |
| device does not receive or pass the transport stream directly. | |
| A point in the stream, suitable for exit, that lies on an elementary | |
| presentation unit boundary. An Out Point is actually between two | |
| presentation units rather than being a presentation unit itself. | |
| A bit in the transport packet header that signals, among other things, | |
| that a section begins in the payload that follows (see [MPEG | |
| Systems]). | |
| A potentially constrained location relative to digital content where ad | |
| insertion or content alterations can occur. The alterations may include | |
| insertions, replacements, or deletions of content in whole or in part. | |
| These locations, which contain the opportunity for content insertion, | |
| have traditionally been referred to as Avails [SCTE35] for linear video | |
| content; however, placement opportunity refers to address and time | |
| locations where content may be placed, regardless of platform (i.e. | |
| Video in VOD, Banner Images on Menus and ITV channels, etc.). | |
| All the packets with the same PID within a transport stream. | |
| The first byte of a transport packet payload, required when a section | |
| begins in that packet (see [MPEG Systems]). | |
| The time that a presentation unit is presented in the system target | |
| decoder (see [MPEG Systems]). | |
| A decoded Audio Access Unit or a decoded picture (see [ITU H.262]). | |
| A collection of video, audio, and data PID streams that share a | |
| common program number within an MPTS (see [MPEG Systems]). As | |
| used in the context of the segmentation descriptor, a performance or | |
| informative presentation broadcast on television, typically with a | |
| duration over 5 minutes (sometimes called "long-form" content). | |
| A group of PID stream In Points that correspond in presentation time. | |
| A group of PID stream Out Points that correspond in presentation | |
| time. | |
| A mode of the cueing message whereby the program_splice_flag is set | |
| to '1', indicating that the message refers to a Program Splice Point and | |
| that all PIDs/components of the program are to be spliced. | |
| | |
| A Program In Point or a Program Out Point. | |
| A Program In Point or a Program Out Point. A device that receives or interprets sections conforming to this | |
| A device that receives or interprets sections conforming to this | |
| A device that receives or interprets sections conforming to this standard. Examples of these devices include splicers, ad servers, | |
| A device that receives or interprets sections conforming to this | |
| | |

| | within this program. The presence of the Registration Descriptor |
|------------------------------------|---|
| | signifies a program's compliance with this standard. |
| reserved | The term "reserved", when used in the clauses defining the coded bit stream, indicates that the value <i>may</i> be used in the future for |
| | extensions to the standard. Unless otherwise specified, all reserved bits |
| | shall be set to '1' and this field shall be ignored by receiving equipment. |
| Segment | Either a <i>Program</i> , a <i>Chapter</i> , a <i>Provider Advertisement</i> , a <i>Distributor Advertisement</i> , or an <i>Unscheduled Event</i> as listed in Table 22, segmentation_type_id. |
| Single Program Transport Stream | A transport stream containing a single MPEG program. |
| Splice Event | An opportunity to splice one or more PID streams. |
| Splice Immediate Mode | A mode of the cueing message whereby the splicing device <i>shall</i> |
| | choose the nearest opportunity in the stream, relative to the |
| | splice_info_table, to splice. When not in this mode, the message gives |
| | a "pts_time" that, when modified by pts_adjustment, gives a |
| | presentation time for the intended splicing moment. |
| Splice Point | A point in a PID stream that is either an Out Point or an In Point. |
| UPID | Identifier for the content or content segment that programmers' systems utilize. |
| Viewing Event | A television program or a span of compressed material within a service; as opposed to a splice event, which is a point in time. |

6. Introduction

6.1. Splice points (Informative)

To enable the splicing of compressed bit streams, this standard defines Splice Points. Splice Points in an MPEG-2 transport stream provide opportunities to switch elementary streams from one source to another. They indicate a place to switch or a place in the bit stream where a switch can be made. Splicing at such splice points *may* or *may* not result in good visual and audio quality. That is determined by the performance of the splicing device.

The use of "advanced" video compression, such as documented by ITU-T H.264/ ISO/IEC 14496-10 ("AVC") or ITU-T H.265/ ISO/IEC 23008-2("HEVC") typically requires advance notice of Splice Points to permit the video encoder to create a spliceable point in the video elementary stream. In most systems this is provided by the use of [SCTE 104] to provide a communications path from the programmer's Automation System to their Compression System. These AVC and HEVC coding constraints for splice points are documented in [SCTE 172].

Transport streams are created by multiplexing PID streams. In this standard, two types of Splice Points for PID streams are defined: Out Points and In Points. In Points are places in the bit streams where it is acceptable to enter, from a splicing standpoint. Out Points are places where it is acceptable to exit the bit stream. The grouping of In Points of individual PID streams into Program In Points in order to enable the switching of entire programs (video with audio) is defined. Program Out Points for exiting a program are also defined.

Out Points and In Points are imaginary points in the bit stream located between two elementary stream presentation units. Out Points and In Points are not necessarily transport packet aligned and are not

necessarily PES packet aligned. An Out Point and an In Point *may* be co-located; that is, a single presentation unit boundary *may* serve as both a safe place to leave a bit stream and a safe place to enter it.

The output of a simple switching operation will contain access unit data from one stream up until its Out Point followed by data from another stream starting with the first access unit following an In Point. More complex splicing operations *may* exist whereby data prior to an Out Point or data after an In Point are modified by a splicing device. Splicing devices *may* also insert data between one stream's Out Point and the other stream's In Point. The behavior of splicing devices will not be specified or constrained in any way by this standard.

6.2. Program splice points (Informative)

Program In Points and Program Out Points are sets of PID stream In Points or Out Points that correspond in presentation time.

Although Splice Points in a Program Splice Point correspond in presentation time, they do not usually appear near each other in the transport stream. Because compressed video takes much longer to decode than audio, the audio Splice Points *may* lag the video Splice Points by as much as hundreds of milliseconds and by an amount that can vary during a program.

This standard defines two ways of signaling which splice points within a program are to be spliced. A program_splice_flag, when true, denotes that the Program Splice Mode is active and that all PIDs of a program *may* be spliced (the splice information table PID is an exception; splicing or passage of these messages is beyond the scope of this standard). A program_splice_flag, when false, indicates that the Component Splice Mode is active and that the message will specify unambiguously which PIDs are to be spliced and *may* give a unique splice time for each. This is required to direct the splicing device to splice or not to splice various unspecified data types as well as video and audio.

While this standard allows for a unique splice time to be given for each component of a program, it is expected that most Component Splice Mode messages will utilize one splice time (a default splice time) for all components as described in section 9. The facility for optionally specifying a separate splice time for each component is intended to be used when one or more components differ significantly in their start or stop time relative to other components within the same message. An example would be a downloaded applet that must arrive at a set-top box several seconds prior to an advertisement.

6.3. Splice events (Informative)

This standard provides a method for in-band signaling of splice events using splice commands to downstream splicing equipment. Signaling a splice event identifies which Splice Point within a stream to use for a splice. A splicing device *may* choose to act or not act upon a signaled event (a signaled event *should* be interpreted as an opportunity to splice; not a command). A splice information table carries the notice of splice event opportunities. Each signaled splice event is analogous to an analog cue tone. The splice information table incorporates the functionality of cue tones and extends it to enable the scheduling of splice events in advance.

This standard establishes that the splice information table is carried on a per-program basis in one or more PID stream(s) with a designated stream_type. The program's splice information PID(s) are designated in the program's Program Map Table (PMT). In this way, the splice information table is switched with the program as it goes through remultiplexing operations. A common stream_type identifies all PID streams that carry splice information tables. Remultiplexers or splicers *may* use this stream_type field to drop splice information prior to sending the transport stream to the end-user device.

The cue injection equipment *may* send messages at intervals that do not indicate a splice point to be used as heartbeat messages which help insure the proper operation of the system. This could be performed by periodically issuing splice_null() messages or by sending encrypted splice_insert messages generated with a key that is not distributed. Since cues are currently sent twice per hour on a typical network, an average interval of 5 minutes would be a reasonable interval. If a message was not received in a 10-minute interval, a receiving device could alarm an operator to a possible system malfunction (such behavior would be implementer dependent).

6.4. Content storage considerations (Informative)

The requirements for identifier uniqueness are written expecting the content to be playing in real time. If the content is stored, then the playback of the content does not place requirements upon the playback equipment to alter any of these identifiers (such as splice_event_id or segmentation_event_id). Downstream equipment parsing the identifiers *should* keep this in mind and, if applicable, rely upon other confirming information before reacting adversely to a seeming violation of the identifier uniqueness requirements of this standard.

This standard provides optional tools to assist with segmenting content into shorter sections which *may* be either chapters or advertisements. See section 10.3.3.

6.5. PID selection

6.5.1. PID selection (Normative)

Splice Information can be carried in multiple PIDs. The maximum number of PIDs that can carry splice information *shall not* exceed 8. These PIDs can be either in the clear (where the transport scrambling_control bits are set to '00') or scrambled by a CA system. Each cue message PID *may* include the cue_identifier_descriptor defined in section 8.2 to describe the splice commands included in the PID. When multiple PIDs are used to carry splice information, the first cue message PID in the Program Map Table *shall* only contain the splice command types 0x00 (splice_null), 0x04 (splice_schedule) and 0x05 (splice_insert). In addition, the splice_event_id *shall* be unique in all splice information PIDs within the program.

6.5.2. PID selection (Informative)

While the use of multiple cue message PIDs is an allowed practice, it *should* be noted that not all equipment *may* respond in the same manner to a stream that contains multiple cue message PIDs. Some equipment *may* limit the number of PIDs that the equipment can pass or receive. If a system utilizes multiple PIDs through various devices with the intention of reaching the set-top, it is suggested that thorough end-to-end testing be performed.

In many systems, the delivery of PIDs that carry splice information beyond the ad insertion equipment in the head-end is not desired. In these systems, the splicing or multiplexing device will drop any or all of these messages (PIDs), so they will not be delivered to the set-top. In other systems, it *may* selectively pass certain PIDs to enable set-top functionality. A third possibility is that the splicing or multiplexing device will aggregate the multiple PIDs that carry splice information into a single PID to handle downstream (set-top) issues with multiple PIDs. The action of ignoring or passing the message is recommended to be a user provisioned item, with a suitable default behavior chosen by the implementer.

The default operation if a splicing or multiplexing device receives a PID based on this specification with the scrambling bits set in the header *should* be to drop that PID and not pass it through to the output. This

ideally *should* be a user provisioned operation, as in some instances this PID *may* be descrambled by a downstream device.

The delivery of messages outside of the receive location to the customer *may* be based on business agreements. An example would be that one programmer wants the cue messages passed to set-tops to enable a targeted advertising method while a different programmer insists that the messages be dropped to ensure that a commercial killer *may* not utilize the messages.

When multiple splicing PIDs are identified in the PMT, the splicing device *should* process all of these PIDs. If the cue_identifier_descriptor is utilized, the splicing or multiplexing device *may* use that information to be more selective of the PIDs on which it will act.

Some possible reasons for utilizing multiple PIDs for this message include selective delivery of cue messages for different tiers of advertising or for separating cue messages from segmentation messages. While one possible method of handling these issues is to use the encryption methods built in to this standard, many delivery mechanisms can support conditional delivery by PID in a secure fashion. The delivery equipment (satellite transmitter/receiver, remultiplexer) *may* PID filter the stream to only allow one or a small number of the PIDs to be passed in-stream. This method *may* be used to create multiple programs in the feed based on entitlement. The decision to use one or more PIDs will be based on the security required and the CA hardware available on the system.

6.6. Message flow (Informative)

The messages described in this document can originate from multiple sources. They are designed to be sent in-stream to downstream devices. The downstream devices *may* act on the messages or send them to a device that is not in-stream to act upon them. An example would be a splicer communicating via SCTE 30 protocol to an ad server (See [SCTE 30]). The in-stream devices could pass the messages to the next device in the transmission chain, or they could, optionally, drop the messages. Implementers are urged to make these decisions user provisioned, rather than arbitrarily hard-coded.

Any device that re-stamps pcr/pts/dts and that passes these cue messages to a downstream device *should* modify the pts_time field or the pts_adjustment field in the message in all PIDs conforming to this standard. Modifying the pts_adjustment field is preferred because the restamping device will not have to be knowledgeable of the pts_time field that *may* occur in multiple commands (and possibly in future commands).

The bandwidth_reservation() message is intended as a message used on a closed path from an origination system (encoder) to a receiver. It is also intended that this message will be dropped (replaced by a NULL packet) by the receiver, but this is not required. *Should* this message reach an in-stream device (e.g., a splicer) the message *should not* be forwarded to an out-of-stream device (e.g., Ad Server) and can either be ignored or passed by an in-stream device. The action of ignoring or passing the message is recommended to be a user provisioned item, with a suitable default behavior chosen by the implementer.

6.7. Usage Examples (Informative)

The following sections are examples on the usage of SCTE 35 for marking various program and advertisement segments. The various SCTE 35 Cueing Messages are typically placed in affiliate programming tiers by the programmer, so an affiliate will only see the cues for which they are authorized. See Section 14 for sample SCTE 35 Messages.

6.7.1. SCTE 35 Ad Break Example

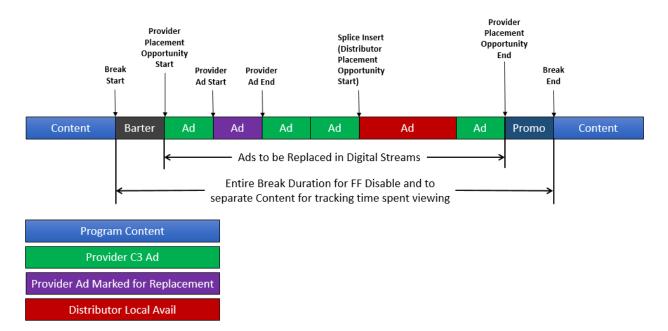

Figure 1 - SCTE 35 Ad Break Example

When a Content Provider inserts non-program content into a program, it typically falls into one of several categories.

- 1) Promotional Items These are clips that usually promote other programming by the programmer or may be public service announcements. In children's programming keeping these intact may be a regulatory matter and they are typically not replaced.
- 2) Barter ads Some programmers purchase content from studios and the studio reserves the right to insert some advertising. As such, these ads are not usually replaceable.
- 3) Provider C3 ad These are programmer inserted advertisements. They are meant to be displayed to a measured audience and may be replaced on devices that are not measured in the traditional sense. Some programmers may use out of band methods such as SCTE 224 to allow these ads to be replaced after a certain amount of time, typically after the C3 windows expires.
- 4) Provider ad marked for replacement One version of addressable advertising sells a particular ad slot to a single advertiser and plays an ad addressed to the most likely viewing demographic audience (network, show, time of day, etc.) in the original programmer feed. It also marks the individual ad for possible addressable replacement if the device is capable and if the audience information to do so is available. One example would be a car company with a minivan ad for a typical family show, but able to switch to a sports car or truck ad if it is known that the targeted demographic is not watching.

5) Distributor Local Avail – This is a legacy distributor break. It should be signaled with a Distributor Placement Opportunity instead of a splice_insert, although currently deployed systems may not work.

Explanation of the SCTE 35 signaling used:

- 1) Break Start/End These are inserted to mark the edges of non-program material. This can be used, for example, to disable fast forward during the break to insure barter ads and others are seen and measured. It could also be used to remove the entire break to repurpose the content for future use.
- 2) Provider Placement Opportunity Start/End These signals mark an entire block of ads that *may* be replaced. The decision to actually replace the entire break is based on many factors including live vs restart vs lookback viewing, device, demographics, etc. If the distributor local avail is embedded inside this break, one should use the MID structure to include information about pod position and length of the local avail; in this way, one will be able to stitch together all of the programmer and distributor ads and any required slate for a seamless user presentation.
- 3) Provider Ad Start/End If a programmer wants to have a downstream system replace an individual ad, they can use this to mark that ad. They would typically use an Ad-ID identifier for the segmentation UPID.
- 4) splice insert This is a legacy construct indicating where the local affiliate breaks occur.

6.7.1. SCTE 35 Program Example

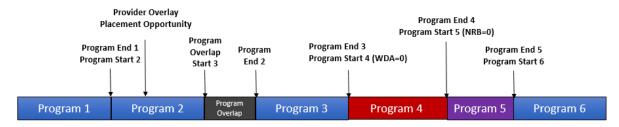

Figure 2 - SCTE 35 Program Example

Ad breaks described in the previous section are typically embedded at various points within the program content; they are not shown in this diagram.

This example shows the segmentation types used to delineate common programming sequences. The programmer should set the segmentation Unique Program Identifier (UPID) to a value that can be cross referenced to the SCTE 224 feed in order to deliver additional information about the program.

WDA is the Web Delivery Allowed flag [See 10.3.3]. Setting this to false (0) indicates that there is a web blackout. An implementer would need to verify exactly what the programmer means by this, but it is typically used to indicate anything delivered to a subscriber over the open internet as opposed to a closed MVPD network.

NRB is the No Regional Blackout flag [See 10.3.3]. When set to false (0), this indicates that this program is subject to a regional blackout. An implementer would, likely, refer to a SCTE 224 feed or a programmer or sports league website to determine the appropriate blackout geography.

6.7.1. SCTE 35 Complex example

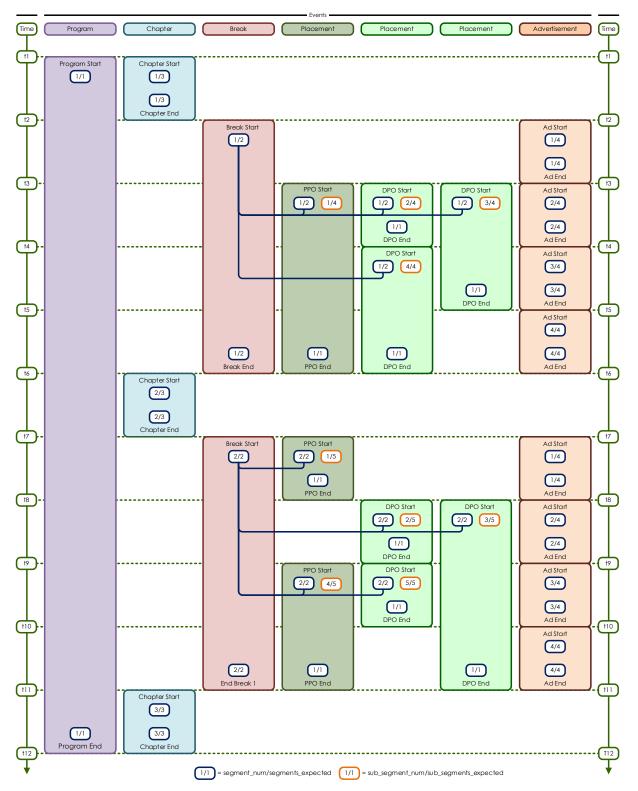

Figure 3 - SCTE 35 Program Example

This is an additional example showing various uses of the distributor placement opportunity in more complex overlapping scenarios.

7. Notational Conventions

7.1. Normative XML schema

Descriptions of elements and attributes are normative and, when combined with the normative XML schema document (provided separately), comprise the full normative schema specification. Unless otherwise specified, the normative text and values assigned to elements or attributes in this specification *shall* be constrained by the bit stream equivalent field.

Non-normative schema illustrations and instance examples are included herein for informational purposes only. Any real or implied usage, semantics, or structure indicated by the schema illustrations and examples *shall not* be considered part of the specification.

No XML documents representing the structures defined in the schema are considered conformant unless they are valid according to the schema document. Additionally, other SCTE 35 standard normative parts *may* impose additional rules or restrictions that *shall* be adhered to in order for XML documents to be considered conformant to those parts.

In the case where this document and the normative schema document (i.e., the separately provided XML 'xsd' file) conflict, this document *shall* take precedence over the XML schema document.

The inclusion of a normative XML schema document does not require or imply the specific use of the schema nor a requirement that an XML document be validated.

If the SCTE 35 schema is used in combination with other schemas, it is recommended to utilize the namespace prefix of "SCTE35". For example, SCTE35:SpliceInsertType to reference an SCTE 35 SpliceInsert Type.

7.2. Unknown/Unrecognized/Unsupported XML elements and attributes

Generally, unknown, unrecognized or unsupported XML elements and attributes contained within SCTE 35 elements *should* be ignored during XML document processing. Specifically, these are elements or attributes which the implementation does not understand or expect. XML parsers that encounter elements or attributes which are prohibited by a namespace *should* include exception handling.

7.3. Element order

Element order is constrained by the schemas and *shall* be preserved throughout processing of the XML document. In particular, the order of elements affects the end result of the processing. Consequently, an implementation failing to preserve the order *may* cause incorrect processing results. Subsequently, the process of producing an abstract XML Information Set (InfoSet) from a concrete XML document, e.g., by parsing it, *shall* always result in the same abstract InfoSet, with the same element order per XML InfoSet (see [XML InfoSet] for additional information). Any intermediary processing *may* enhance the XML document but it *shall not* alter the abstract InfoSet element order (i.e., the XML elements comprising the document *shall* stay in document order).

7.4. Binary representation in XML

The content of a SpliceInfoSection (See 9.6) *may* be represented in XML as either a fully parsed structure or as a binary representation. This choice is provided in the XML Schema as a Signal group (Figure 4). The binary representation *shall* be Base64 encoded per [RFC 4648]. The Binary element *should* be assumed to contain a SpliceInfoSection unless explicitly indicated by the signalType attribute as something else. The signalType attribute is provided to allow some flexibility in how the XML Schema is used for binary representations. Whenever the value of signalType is not "SpliceInfoSection" it *shall* be prefixed with the text "private:"

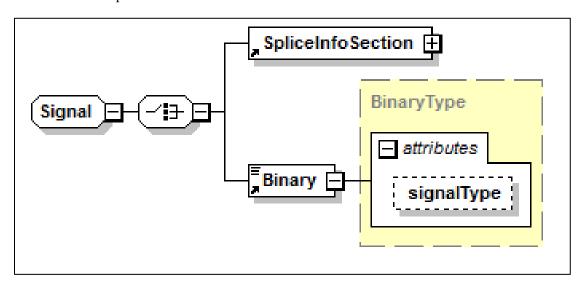

Figure 4 - SignalGroup

8. PMT Descriptors

8.1. Registration descriptor

The registration descriptor (see [MPEG Systems], table 2-46 – Registration Descriptor, clause 2.6.8) is defined to identify unambiguously the programs that comply with this standard. The registration descriptor *shall* be carried in the program_info loop of the PMT for each program that complies with this standard. It *shall* reside in all PMTs of all complying programs within a multiplex. The presence of the registration descriptor also indicates that, when signaling splice events, splice_info_sections *shall* be carried in one or more PID stream(s) within this program.

Presence of this registration descriptor in the PMT signals the following:

- 1. The program elements do not include the splice information table defined by [SMPTE 312].
- 2. The only descriptors that can be present in the ES_descriptor_loop of the PMT for the PID(s) that carry the splice_information_table are those that are defined in this specification or user private descriptors.

Note that this descriptor applies to the indicated program and not to the entire multiplex. The content of the registration descriptor is specified in Table 1 and below:

Table 1 - registration_descriptor()

| Syntax | Bits | Mnemonic |
|--|--------------|----------------------------|
| registration descriptor() { descriptor tag descriptor length SCTE splice format identifier } | 8 8 32 | uimsbf uimsbf uimsbf |

8.1.1. Semantic definition of fields in Registration Descriptor

descriptor_tag – The descriptor_tag is an 8-bit field that identifies each descriptor. For registration purposes, this field *shall* be set to 0x05.

descriptor_length – The descriptor_length is an 8-bit field specifying the number of bytes of the descriptor immediately following descriptor_length field. For this registration descriptor, descriptor_length *shall* be set to 0x04.

SCTE_splice_format_identifier – SCTE has assigned a value of 0x43554549 (ASCII "CUEI") to this 4-byte field to identify the program (within a multiplex) in which it is carried as complying with this standard.

8.2. Cue Identifier Descriptor

The cue_identifier_descriptor *may* be used in the PMT to label PIDs that carry splice commands so that they can be differentiated as to the type or level of splice commands they carry. The cue_identifier_descriptor, when present, *shall* be located in the elementary descriptor loop. If the cue_identifier_descriptor is not utilized, the stream *may* carry any valid command in this specification.

Table 2 - cue_identifier_descriptor()

| Syntax | Bits | Mnemonic |
|--|-------------|----------------------------|
| <pre>cue identifier descriptor() { descriptor tag descriptor length cue stream type }</pre> | 8 8 8 | uimsbf uimsbf uimsbf |

8.2.1. Semantic definition of fields in Cue Identifier Descriptor

descriptor_tag – The descriptor_tag is an 8-bit field that identifies each descriptor. For cue_identifier_descriptor, this field *shall* be set to 0x8A.

descriptor_length – The descriptor_length in an 8-bit field specifying the number of bytes of the descriptor immediately following descriptor_length field. For this descriptor, descriptor_length *shall* be set to 0x01.

cue_stream_type – This 8-bit field is defined in Table 3.

Table 3 - cue_stream_type values

| cue_stream_type | PID usage |
|-----------------|---|
| 0x00 | splice_insert, splice_null, splice_schedule |
| 0x01 | All Commands |
| 0x02 | Segmentation |
| 0x03 | Tiered Splicing |
| 0x04 | Tiered Segmentation |
| 0x05-0x7f | Reserved |
| 0x80 - 0xff | User Defined |

8.2.2. Description of cue stream type usage

0x00 – **splice_insert**, **splice_null**, **splice_schedule** – Only these cue messages are allowed in this PID stream. There **shall** be a maximum of one PID identified with this cue_stream_type. If this PID exists, it **shall** be the first stream complying with this standard in the PMT elementary stream loop.

0x01 – All Commands – Default if this descriptor is not present. All messages can be used in this PID.

0x02 – **Segmentation** – This PID carries the time_signal command and the segmentation descriptor. It *may* also carry all other commands if needed for the application, but the primary purpose is to transmit content segmentation information.

0x03 – **Tiered Splicing** – Tiered Splicing refers to an insertion system where the operator provides different inserted program possibilities in a given avail for different customers. The physical and logical implementation *may* be done in several different manners, some of them outside the scope of this standard.

0x04 – **Tiered Segmentation** – Tiered Segmentation refers to a system where the operator provides different program segmentation possibilities for different customers. The physical and logical implementation *may* be done in several different manners, some of them outside the scope of this standard.

0x05-0x7F – Reserved for future extensions to this standard.

0x80-0xFF – User defined range.

8.3. Stream Identifier Descriptor

The stream identifier descriptor *may* be used in the PMT to label component streams of a service so that they can be differentiated. The stream identifier descriptor *shall* be located in the elementary descriptor loop following the relevant ES_info_length field. The stream identifier descriptor *shall* be used if either the program_splice_flag or the program_segmentation_flag is zero. If stream identifier descriptors are used, a stream identifier descriptor *shall* be present in each occurrence of the elementary stream loop within the PMT and *shall* have a unique component tag within the given program.

Table 4 - stream_identifier_descriptor()

| Syntax | Bits | Mnemonic |
|----------------------------------|------|----------|
| stream_identifier_descriptor() { | | |
| descriptor tag | 8 | uimsbf |
| descriptor length | 8 | uimsbf |
| component tag | 8 | uimsbf |
| } | | |

8.3.1. Semantic definition of fields in Stream Identifier Descriptor

descriptor_tag – The descriptor_tag is an 8-bit field that identifies each descriptor. For stream identifier descriptor, this field **shall** be set to 0x52.

descriptor_length – The descriptor_length in an 8-bit field specifying the number of bytes of the descriptor immediately following descriptor_length field. For this descriptor, descriptor_length *shall* be set to 0x01.

component_tag – This 8-bit field identifies the component stream for associating it with a description given in a component descriptor. Within a program map section each stream identifier descriptor *shall* have a different value for this field.

9. Splice information table

9.1. Overview

The splice information table provides command and control information to the splicer. It notifies the splicer of splice events in advance of those events. It is designed to accommodate ad insertion in network feeds. In this environment, examples of splice events would include 1) a splice out of a network feed into an ad, or 2) the splice out of an ad to return to the network feed. The splice information table *may* be sent multiple times and splice events *may* be cancelled. Syntax for a splice_info_section is defined to convey the splice information table. The splice_info_section is carried on one or more PID stream(s) with the PID(s) declared in that program's PMT.

A splice event indicates the opportunity to splice one or more elementary streams within a program. Each splice event is uniquely identified with a splice_event_id. Splice events *may* be communicated in three ways: they *may* be scheduled ahead of time, a pre-roll warning *may* be given, or a command *may* be given to execute the splice event at specified Splice Points. These three types of messages are sent via the splice_info_section. The splice_command_type field specifies the message being sent. Depending on the value of this field, different constraints apply to the remaining syntax.

The following command types are specified: splice_null(), splice_schedule(), splice_insert(), time_signal() and bandwidth_reservation(). If the Receiving Device does not support a command, it can ignore the entire splice info section.

The splice_null(), splice_schedule() and splice_insert() are the legacy commands used in this standard and there is substantial installed base that expects to use these commands in order to perform ad insertions. An alternative mechanism is defined using the time_signal() command to signal splice events in new applications where there is control over the installed equipment.

9.2. Legacy Command Descriptions

The splice_null() command is provided for extensibility. It can be used as a means of providing a heartbeat message to downstream splicing equipment.

The splice_schedule() command is a command that allows a schedule of splice events to be conveyed in advance.

The splice_insert() command *shall* be sent at least once before each legacy splice point. Packets containing the entirety of the splice_info_table *shall* always precede the packet that contains the related splice point (i.e., the first packet that contains the first byte of an access unit whose presentation time most closely matches the signaled time in the splice info section).

In order to give advance warning of the impending splice (a pre-roll function), the splice_insert() command could be sent multiple times before the splice point. For example, the splice_insert() command could be sent at 8, 5, 4 and 2 seconds prior to the packet containing the related splice point. In order to meet other splicing deadlines in the system, any message received with less than 4 seconds of advance notice *may* not create the desired result. The splice_insert() message *shall* be sent at least once a minimum of 4 seconds in advance of the desired splice time for a network Out Point condition. It is recommended that, if a return-to-network (an In Point) message is sent, the same minimum 4 second pre-roll be provided.

The splice_insert() command provides for an optional break_duration() structure to identify the length of the commercial break. It is recommended that splice_insert() messages with the out_of_network_indicator set to 1 (a network Out Point) include a break_duration() structure to provide the splicer with an indication of when the network In Point will occur. The break_duration() structure provides for an optional auto_return flag that, when set to 1, indicates that the splicer is to return to the network at the end of the break (defined as Auto Return Mode, refer to section 9.9.2.2). It is recommended that this Auto Return Mode be used to support dynamic avail durations.

The bandwidth_reservation() command is provided to allow command insertion devices to utilize a consistent amount of transport stream bandwidth. Descriptors *may* be used in this command, but they cannot be expected to be processed and sent downstream to provide signaling information.

9.3. Time Signal Command

The time_signal() command is provided for extensibility by adding descriptors while preserving the precise timing allowed in the splice_insert() command. This is to allow for new features utilizing the timing capabilities of this specification while causing minimal impact to the splicing devices that conform to this specification.

A splice_insert() command typically instructs an encoder to condition the stream for a splice event. When a time_signal() command is used to signal splice events, it *shall* carry one or more segmentation descriptors() with additional information to determine what *may* need to be done to the stream. For example, a segmentation_descriptor() with a Provider Placement Opportunity or Program Start would likely indicate that the stream should be conditioned at the time indicated. There *may* also be out of band communications that can control the implementation for example [SCTE 224] and/or [SCTE 250].

9.4. Command Changes

There are two methods for changing the parameters of a command once it has been issued. One method is to cancel the issued command by sending a splice info section with the splice event cancel indicator set

and then to send a new splice_info_section with the correct/new parameters. The other method is to simply send a subsequent message with the new data (without canceling the old message via a cue message that has the splice event cancel indicator bit set).

9.5. Time base discontinuities

In the case where a system time base discontinuity is present, packets containing a splice_insert() or time_signal() command with time expressed in the new time base *shall not* arrive prior to the occurrence of the time base discontinuity. Packets containing a splice_insert() or time_signal() command with time expressed in the previous time base *shall not* arrive after the occurrence of the time base discontinuity. See [ISO 13818–4].

The complete syntax is presented below, followed by definition of terms, followed by constraints.

9.6. Splice info section

The splice_info_section *shall* be carried in transport packets whereby only one section or partial section *may* be in any transport packet. Splice_info_sections *shall* always start at the beginning of a transport packet payload. When a section begins in a transport packet and this is the first packet of the splice_info_section, the pointer_field *shall* be present and equal to 0x00 and the payload_unit_start_indicator bit *shall* be equal to one (per the requirements of section syntax usage per [MPEG Systems]).

The XML schema for splice_info_section is shown in Figure 5.

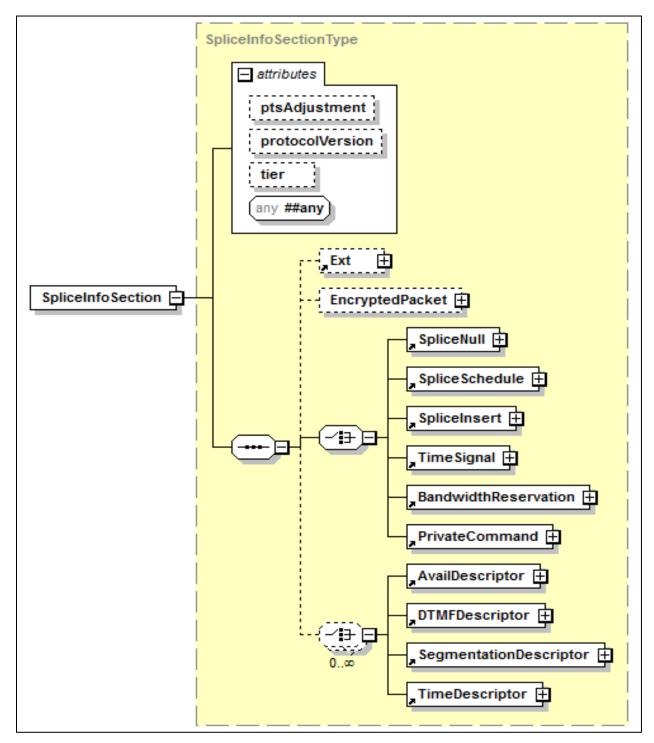

Figure 5 - SpliceInfoSection

9.6.1. Semantic definition of fields in splice_info_section()

table_id - This is an 8-bit field. Its value *shall* be 0xFC.

There is no entry in the XML schema for table_id. The value is implicit when transforming to or from an XML representation of the splice info section.

section_syntax_indicator – The section_syntax_indicator is a 1-bit field that *should* always be set to '0', indicating that MPEG short sections are to be used.

There is no entry in the XML schema for section_syntax_indicator. The value is a constant when converting an XML representation of the splice info section to Bit Stream Format.

private indicator – This is a 1-bit flag that *shall* be set to 0.

There is no entry in the XML schema for private_indicator. The value is a constant when converting an XML representation of the splice_info_section to Bit Stream Format.

section_length – This is a 12-bit field specifying the number of remaining bytes in the splice_info_section, immediately following the section_length field up to the end of the splice info section. The value in this field **shall not** exceed 4093.

There is no entry in the XML schema for section_length. The value *shall* be derived when converting an XML representation of the splice info section to Bit Stream Format.

protocol_version – An 8-bit unsigned integer field whose function is to allow, in the future, this table type to carry parameters that *may* be structured differently than those defined in the current protocol. At present, the only valid value for protocol_version is zero. Non-zero values of protocol_version *may* be used by a future version of this standard to indicate structurally different tables.

@protocolVersion [Optional; xsd:unsignedByte] If present, this attribute *shall* be set to 0.

encrypted_packet – When this bit is set to '1', it indicates that portions of the splice_info_section, starting with splice_command_type and ending with and including E_CRC_32, are encrypted. When this bit is set to '0', no part of this message is encrypted. The potentially encrypted portions of the splice info table are indicated by an E in the Encrypted column of Table 5.

There is no entry in the XML schema for encrypted_packet. When converting an XML representation of the splice_info_section to Bit Stream Format, this value *shall* be set to 1 if the EncryptedPacket Element is present; otherwise, the value *shall* be set to 0. When creating the SpliceInfoSection Element, the EncryptedPacket Element *shall* be populated if encryption is desired. The encrypted attributes *shall* only apply to the generation of the Bit Stream Format of the splice_info_section. The encrypted attributes may be populated when converting a splice_info_section to XML, but the actual data in the XML *shall not* be encrypted.

encryption_algorithm – This 6-bit unsigned integer specifies which encryption algorithm was used to encrypt the current message. When the encrypted_packet bit is zero, this field is present but undefined. Refer to section 11, and specifically Table 27 - Encryption algorithm, for details on the use of this field.

@encryptionAlgorithm [Conditional Mandatory, xsd:unsignedByte] If the EncryptedPacket Element is present this value *shall* be provided.

pts_adjustment – A 33-bit unsigned integer that appears in the clear and that **shall** be used by a splicing device as an offset to be added to the (sometimes) encrypted pts_time field(s) throughout this message, to obtain the intended splice time(s). When this field has a zero value, then the pts_time field(s) **shall** be used without an offset. Normally, the creator of a cueing message will place a zero value into this field.

This adjustment value is the means by which an upstream device, which restamps pcr/pts/dts, *may* convey to the splicing device the means by which to convert the pts_time field of the message to a newly imposed time domain.

It is intended that the first device that restamps pcr/pts/dts and that passes the cueing message will insert a value into the pts_adjustment field, which is the delta time between this device's input time domain and its output time domain. All subsequent devices, which also restamp pcr/pts/dts, *may* further alter the pts_adjustment field by adding their delta time to the field's existing delta time and placing the result back in the pts_adjustment field. Upon each alteration of the pts_adjustment field, the altering device *shall* recalculate and update the CRC 32 field.

The pts_adjustment *shall*, at all times, be the proper value to use for conversion of the pts_time field to the current time-base. The conversion is done by adding the two fields. In the presence of a wrap or overflow condition, the carry *shall* be ignored.

@ptsAdjustment [Optional, PTSType] See section 13.2.

cw_index – An 8-bit unsigned integer that conveys which control word (key) is to be used to decrypt the message. The splicing device *may* store up to 256 keys previously provided for this purpose. When the encrypted packet bit is zero, this field is present but undefined.

@cwIndex [Conditional Mandatory, xsd:unsignedByte] If the EncryptedPacket Element is present this value *shall* be provided.

tier – A 12-bit value used by the SCTE 35 message provider to assign messages to authorization tiers. This field *may* take any value between 0x000 and 0xFFF. The value of 0xFFF provides backwards compatibility and *shall* be ignored by downstream equipment. When using tier, the message provider *should* keep the entire message in a single transport stream packet.

@tier [Optional, xsd:unsignedShort]

splice_command_length – A 12-bit length of the splice command. The length **shall** represent the number of bytes following the **splice_command_type** up to, but not including the **descriptor_loop_length**. Devices that are compliant with this version of the standard **shall** populate this field with the actual length. The value of 0xFFF provides backwards compatibility and **shall** be ignored by downstream equipment.

There is no entry in the XML schema for splice_command_length. The value *shall* be derived when converting an XML representation of the splice_info_section to Bit Stream Format.

splice_command_type – An 8-bit unsigned integer which *shall* be assigned one of the values shown in column labeled splice_command_type value in Table 6.

There is no entry in the XML schema for splice_command_type. The value is implicit when transforming to or from an XML representation of the splice_info_section based on the specific command Element supplied. The Element names can be found in the XML Element column in Table 6.

Table 6 - splice_command_type values

| Command | splice_command_type value | XML Element |
|-----------------------|---------------------------|----------------------|
| splice_null | 0x00 | SpliceNull |
| Reserved | 0x01 | |
| Reserved | 0x02 | |
| Reserved | 0x03 | |
| splice_schedule | 0x04 | SpliceSchedule |
| splice_insert | 0x05 | SpliceInsert |
| time_signal | 0x06 | TimeSignal |
| bandwidth_reservation | 0x07 | BandwidthReservation |
| Reserved | 0x08 - 0xfe | |
| private_command | 0xff | PrivateCommand |

descriptor_loop_length – A 16-bit unsigned integer specifying the number of bytes used in the splice descriptor loop immediately following.

There is no entry in the XML schema for descriptor_loop_length. The value *shall* be derived when converting an XML representation of the splice info section to Bit Stream Format.

alignment_stuffing — When encryption is used, this field is a function of the particular encryption algorithm chosen. Since some encryption algorithms require a specific length for the encrypted data, it is necessary to allow the insertion of stuffing bytes. For example, DES requires a multiple of 8 bytes be present in order to encrypt to the end of the packet. This allows standard DES to be used, as opposed to requiring a special version of the encryption algorithm.

When encryption is not used, this field *shall not* be used to carry valid data, but may be present.

There is no entry in the XML schema for alignment_stuffing. The required data *shall* be derived when converting an XML representation of the splice info section to Bit Stream Format.

E_CRC_32 – This is a 32-bit field that contains the CRC value that gives a zero output of the registers in the decoder defined in [MPEG Systems] after processing the entire decrypted portion of the splice_info_section. This field is intended to give an indication that the decryption was performed successfully. Hence, the zero output is obtained following decryption and by processing the fields splice_command_type through E_CRC_32.

There is no entry in the XML schema for E_CRC_32. The value *shall* be derived when converting an XML representation of the splice info section to Bit Stream Format.

CRC_32 – This is a 32-bit field that contains the CRC value that gives a zero output of the registers in the decoder defined in [MPEG Systems] after processing the entire splice_info_section, which includes the table_id field through the CRC_32 field. The processing of CRC_32 *shall* occur prior to decryption of the encrypted fields and *shall* utilize the encrypted fields in their encrypted state.

There is no entry in the XML schema for CRC_32. The value *shall* be derived when converting an XML representation of the splice info section to Bit Stream Format.

9.7. Splice commands

9.7.1. splice null()

The splice_null() command is provided for extensibility of the standard. The splice_null() command allows a splice_info_table to be sent that can carry descriptors without having to send one of the other defined commands. This command *may* also be used as a "heartbeat message" for monitoring cue injection equipment integrity and link integrity.

Table 7 - splice_null()

| Syntax | Bits | Mnemonic |
|-----------------|------|----------|
| splice_null() { | | |
| } | | |

The XML schema for splice null is shown in Figure 6.

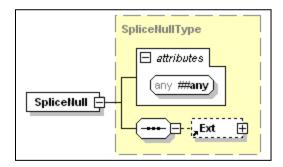

Figure 6 - SpliceNull

9.7.2. splice schedule()

The splice_schedule() command is provided to allow a schedule of splice events to be conveyed in advance.

Table 8 - splice_schedule()

| Syntax | Bits | Mnemonic |
|---|------|----------|
| <pre>splice_schedule() {</pre> | | |
| splice_count | 8 | uimsbf |
| for (i=0; i <splice_count; i++)="" td="" {<=""><td></td><td></td></splice_count;> | | |
| splice_event_id | 32 | uimsbf |
| splice_event_cancel_indicator | 1 | bslbf |
| reserved | 7 | bslbf |
| if (splice_event_cancel_indicator == '0') { | | |
| out_of_network_indicator | 1 | bslbf |
| program_splice_flag | 1 | bslbf |
| duration_flag | 1 | bslbf |
| reserved | 5 | bslbf |
| if (program_splice_flag == '1') | | |
| utc_splice_time | 32 | uimsbf |
| if (program_splice_flag == '0') { | | |
| component_count | 8 | uimsbf |
| for(j=0;j <component_count;j++) td="" {<=""><td></td><td></td></component_count;j++)> | | |
| component_tag | 8 | uimsbf |
| utc_splice_time | 32 | uimsbf |
| } | | |
| } | | |
| if (duration_flag) | | |
| break_duration() | | |
| unique_program_id | 16 | uimsbf |
| avail_num | 8 | uimsbf |
| avails_expected | 8 | uimsbf |
| } | | |
| } | | |
| [} | | |

The XML schema for splice schedule is shown in Figure 7.

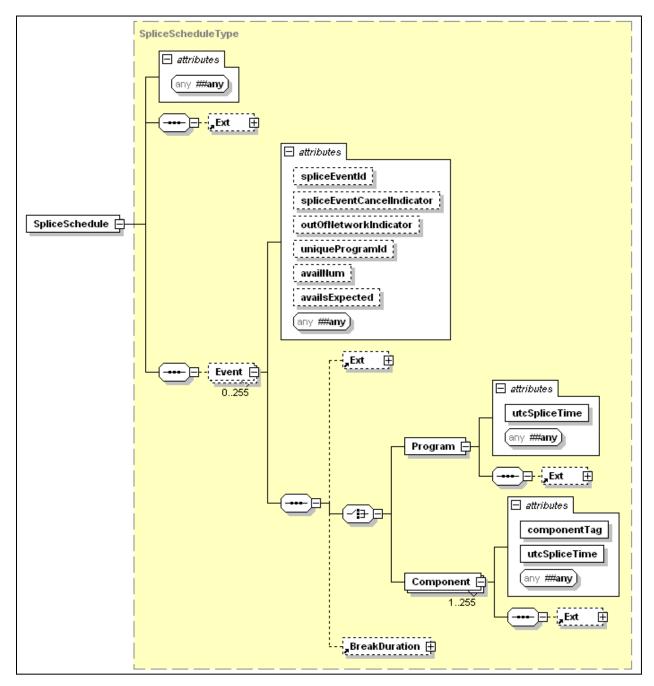

Figure 7 - SpliceSchedule

9.7.2.1. Semantic definition of fields in splice_schedule()

splice_count – An 8-bit unsigned integer that indicates the number of splice events specified in the loop that follows.

There is no entry in the XML schema for splice_count. The value *shall* be derived when converting an XML representation of the splice_schedule to Bit Stream Format. splice_count *shall* be set to the count of Event Elements supplied in the XML document.

splice event id – A 32-bit unique splice event identifier.

@spliceEventId [Optional, xsd:unsignedInt]

splice_event_cancel_indicator – A 1-bit flag that, when set to '1', indicates that a previously sent splice event, identified by splice event id, has been cancelled.

@spliceEventCancelIndicator [Optional; xsd:boolean] A value of TRUE *shall* be equivalent to a value of '1' and FALSE *shall* be equivalent to a value of '0'. If omitted, set splice_event_cancel_indicator to 0 when generating an SCTE 35 splice schedule message.

out_of_network_indicator — A 1-bit flag that, when set to '1', indicates that the splice event is an opportunity to exit from the network feed and that the value of utc_splice_time *shall* refer to an intended Out Point or Program Out Point. When set to '0', the flag indicates that the splice event is an opportunity to return to the network feed and that the value of utc_splice_time *shall* refer to an intended In Point or Program In Point.

@outOfNetworkIndicator [Optional, xsd:boolean] A value of TRUE *shall* be equivalent to a value of '1' for out of network indicator in Bit Stream Format.

program_splice_flag – A 1-bit flag that, when set to '1', indicates that the message refers to a Program Splice Point and that the mode is the Program Splice Mode whereby all PIDs/components of the program are to be spliced. When set to '0', this field indicates that the mode is the Component Splice Mode whereby each component that is intended to be spliced will be listed separately by the syntax that follows.

There is no entry in the XML schema for program_splice_flag. The value of program_splice_flag *shall* be set to '1' when converting an XML representation of the splice_schedule to Bit Stream Format if the Program Element in the Event Element is specified; otherwise, the value of program_splice_flag *shall* be set to '0'.

duration flag – A 1-bit flag that indicates the presence of the break duration() field.

There is no entry in the XML schema for duration_flag. The value *shall* be derived when converting an XML representation of the splice_schedule to Bit Stream Format. duration_flag *shall* be set to '1' if a BreakDuration Element is supplied within the Event Element; otherwise, duration_flag *shall* be set to '0'. See section 9.8.2 for a description of the BreakDuration Element.

utc_splice_time – A 32-bit unsigned integer quantity representing the time of the signaled splice event as the number of seconds since 00 hours UTC, January 6th, 1980, with the count of intervening leap seconds included. The utc_splice_time *may* be converted to UTC without the use of the GPS_UTC_offset value provided by the System Time table. The utc_splice_time field is used only in the splice_schedule() command.

@utcSpliceTime [Required, xsd:dateTime] utcSplice time applies to both Program Splice Mode and Component Splice Mode.

component_count – An 8-bit unsigned integer that specifies the number of instances of elementary PID stream data in the loop that follows. Components are equivalent to elementary PID streams. If program splice flag == '0' then the value of component count **shall** be greater than or equal to 1.

There is no entry in the XML schema for component_count. For Component Splice Mode, the value *shall* be derived when converting an XML representation of the splice_schedule to Bit Stream Format. component_count *shall* be set to the count of Component Elements supplied within the Event Element in the XML document.

component_tag – An 8-bit value that identifies the elementary PID stream containing the Splice Point specified by the value of splice_time() that follows. The value *shall* be the same as the value used in the stream_identifier_descriptor() to identify that elementary PID stream.

@componentTag [Required, xsd:unsignedByte]

unique_program_id – This value *should* provide a unique identification for a viewing event within the service. Note: See [SCTE 118-2] or [SCTE 224] for guidance in setting values for this field.

@uniqueProgramId [Optional, xsd:unsignedShort]

avail_num – (previously 'avail') This field provides an identification for a specific avail within one unique_program_id. This value is expected to increment with each new avail within a viewing event. This value is expected to reset to one for the first avail in a new viewing event. This field is expected to increment for each new avail. It *may* optionally carry a zero value to indicate its non-usage.

@availNum [Optional, xsd:unsignedByte]

avails_expected – (previously 'avail_count') This field provides a count of the expected number of individual avails within the current viewing event. When this field is zero, it indicates that the avail_num field has no meaning.

@availsExpected [Optional, xsd:unsignedByte]

9.7.3. splice_insert()

The splice_insert() command *shall* be sent at least once for every splice event. Please reference section 6.3 for the use of this message.

Table 9 - splice_insert()

| Syntax | Bits | Mnemonic |
|--|------|----------|
| splice_insert() { | | |
| splice_event_id | 32 | uimsbf |
| splice_event_cancel_indicator | 1 | bslbf |
| reserved | 7 | bslbf |
| if(splice_event_cancel_indicator == '0') { | | |
| out_of_network_indicator | 1 | bslbf |
| program_splice_flag | 1 | bslbf |
| duration_flag | 1 | bslbf |
| splice_immediate_flag | 1 | bslbf |
| reserved | 4 | bslbf |
| <pre>if((program_splice_flag == '1') && (splice_immediate_flag == '0')) splice_time()</pre> | | |
| if(program_splice_flag == '0') { | | |
| component_count | 8 | uimsbf |
| for(i=0;i <component_count;i++) td="" {<=""><td></td><td></td></component_count;i++)> | | |
| component_tag | 8 | uimsbf |
| if(splice_immediate_flag == '0') | | |
| splice_time() | | |
| } | | |
| } | | |
| if(duration_flag == '1') | | |
| break_duration() | | |
| unique_program_id | 16 | uimsbf |
| avail_num | 8 | uimsbf |
| avails_expected | 8 | uimsbf |
| [} | | |
| } | | |

The XML schema for splice_insert is shown in Figure 8.

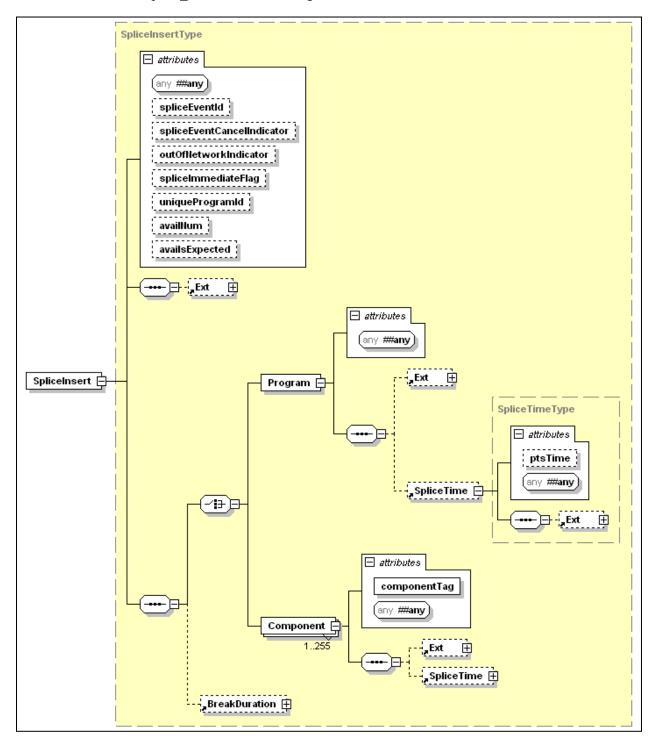

Figure 8 - SpliceInsert

9.7.3.1. Semantic definition of fields in splice_insert()

splice_event_id – A 32-bit unique splice event identifier.

@spliceEventId [Optional; xsd:unsignedInt]

splice_event_cancel_indicator – A 1-bit flag that, when set to '1', indicates that a previously sent splice event, identified by splice_event_id, has been cancelled.

@spliceEventCancelIndicator [Optional; xsd:boolean] A value of TRUE **shall** be equivalent to a value of '1' and FALSE **shall** be equivalent to a value of '0'. If omitted, set splice_event_cancel_indicator to 0 when generating an SCTE 35 splice insert message.

out_of_network_indicator — A 1-bit flag that, when set to '1', indicates that the splice event is an opportunity to exit from the network feed and that the value of splice_time(), as modified by pts_adjustment, shall refer to an intended Out Point or Program Out Point. When set to '0', the flag indicates that the splice event is an opportunity to return to the network feed and that the value of splice time(), as modified by pts_adjustment, shall refer to an intended In Point or Program In Point.

@outOfNetworkIndicator [Optional; xsd:boolean]

program_splice_flag – A 1-bit flag that, when set to '1', indicates that the message refers to a Program Splice Point and that the mode is the Program Splice Mode whereby all PIDs/components of the program are to be spliced. When set to '0', this field indicates that the mode is the Component Splice Mode whereby each component that is intended to be spliced will be listed separately by the syntax that follows.

There is no entry in the XML schema for program_splice_flag. The value of program_splice_flag **shall** be set to '1' when converting an XML representation of the splice_insert to Bit Stream Format if the Program Element in the Event Element is specified; otherwise, the value of program_splice_flag **shall** be set to '0'.

duration flag – A 1-bit flag that, when set to '1', indicates the presence of the break duration() field.

There is no entry in the XML schema for duration_flag. The value *shall* be derived when converting an XML representation of the splice_insert to Bit Stream Format. duration_flag *shall* be set to '1' if a BreakDuration Element is supplied within the SpliceInsert Element; otherwise, duration_flag *shall* be set to '0'. See section 9.8.2 for a description of the BreakDuration Element.

splice_immediate_flag —When this flag is '1', it indicates the absence of the splice_time() field and that the splice mode *shall* be the Splice Immediate Mode, whereby the splicing device *shall* choose the nearest opportunity in the stream, relative to the splice information packet, to splice. When this flag is '0', it indicates the presence of the splice_time() field in at least one location within the splice_insert() command.

@spliceImmediateFlag [Optional; xsd:boolean]

component_count – An 8-bit unsigned integer that specifies the number of instances of elementary PID stream data in the loop that follows. Components are equivalent to elementary PID streams. If program splice flag == '0' then the value of component count **shall** be greater than or equal to 1.

There is no entry in the XML schema for component_count. For Component Splice Mode, the value *shall* be derived when converting an XML representation of the splice_insert to Bit Stream Format. component_count *shall* be set to the count of Component Elements supplied within the SpliceInsert Element in the XML document.

component_tag – An 8-bit value that identifies the elementary PID stream containing the Splice Point specified by the value of splice_time() that follows. The value *shall* be the same as the value used in the stream identifier descriptor() to identify that elementary PID stream.

@componentTag [Required, xsd:unsignedByte]

unique_program_id – This value *should* provide a unique identification for a viewing event within the service. Note: See [SCTE 118-2] for guidance in setting values for this field.

@uniqueProgramId [Optional; xsd:unsignedShort]

avail_num – (previously 'avail') This field provides an identification for a specific avail within one unique_program_id. This value is expected to increment with each new avail within a viewing event. This value is expected to reset to one for the first avail in a new viewing event. This field is expected to increment for each new avail. It *may* optionally carry a zero value to indicate its non-usage.

@availNum [Optional, xsd:unsignedByte]

avails_expected – (previously 'avail_count') This field provides a count of the expected number of individual avails within the current viewing event. When this field is zero, it indicates that the avail field has no meaning.

@availsExpected [Optional, xsd:unsignedByte]

9.7.4. time_signal()

The time_signal() provides a time synchronized data delivery mechanism. The syntax of the time_signal() allows for the synchronization of the information carried in this message with the System Time Clock (STC). The unique payload of the message is carried in the descriptor, however the syntax and transport capabilities afforded to splice_insert() messages are also afforded to the time_signal(). The carriage however can be in a different PID than that carrying the other cue messages used for signaling splice points.

If the time_specified_flag is set to 0, indicating no pts_time in the message, then the command *shall* be interpreted as an immediate command. It must be understood that using it in this manner will cause an unspecified amount of accuracy error.

Note: Since the time_signal() command utilizes descriptors for most of the specific information, this command could exceed one MPEG transport packet in length. Implementors are warned that legacy equipment may require this command to completely fit in one transport packet. This will not always be possible in some situations, for example, where the unique information is long or where another specification is used for the definition of this unique information.

Table 10 - time_signal()

| Syntax | Bits | Mnemonic |
|-----------------|------|----------|
| time_signal() { | | |
| splice_time() | | |
| } | | |

The XML schema for time signal is shown in Figure 9.

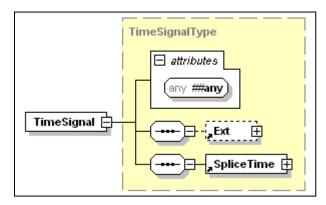

Figure 9 - TimeSignal

9.7.4.1. Semantic definition of time_signal()

The time_signal() provides a uniform method of associating a pts_time sample with an arbitrary descriptor (or descriptors) as provided by the splice_info_section syntax (see Table 5). Please refer to section 10 for Splice Descriptors.

9.7.5. bandwidth reservation()

The bandwidth_reservation() command is provided for reserving bandwidth in a multiplex. A typical usage would be in a satellite delivery system that requires packets of a certain PID to always be present at the intended repetition rate to guarantee a certain bandwidth for that PID. This message differs from a splice_null() command so that it can easily be handled in a unique way by receiving equipment (i.e. removed from the multiplex by a satellite receiver). If a descriptor is sent with this command, it can not be expected that it will be carried through the entire transmission chain and it *should* be a private descriptor that is utilized only by the bandwidth reservation process.

Table 11 - bandwidth_reservation()

| Syntax | Bits | Mnemonic |
|---------------------------|------|----------|
| bandwidth_reservation() { | | |
| } | | |

The XML schema for bandwidth_reservation is shown in Figure 10.

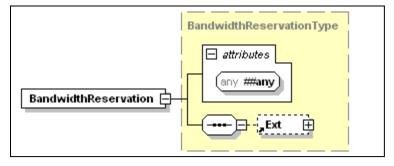

Figure 10 - BandwidthReservation

9.7.6. private command()

The private_command() structure provides a means to distribute user-defined commands using the SCTE 35 protocol. The first bit field in each user-defined command is a 32-bit identifier, unique for each participating vendor. Receiving equipment *should* skip any splice_info_section() messages containing private command() structures with unknown identifiers.

| Table 12 - | private | command() |
|--------------------|---------|-----------|
| | | |

| Syntax | Bits | Mnemonic |
|--|------|----------|
| private_command() { | | |
| identifier | 32 | uimsbf |
| for(i=0; i <n; i++)="" th="" {<=""><th></th><th></th></n;> | | |
| private_byte | 8 | uimsbf |
| } | | |
| } | | |

The XML schema for private command is shown in Figure 11.

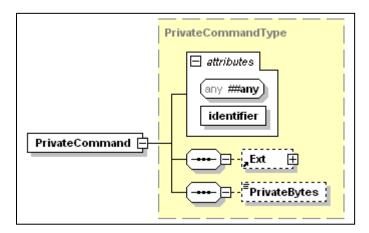

Figure 11 - PrivateCommand

identifier – The identifier is a 32-bit field as defined in ISO/IEC 13818-1 [MPEG Systems], section 2.6.8 and 2.6.9, for the registration_descriptor() format_identifier. Only identifier values registered and recognized by SMPTE Registration Authority, LLC *should* be used (See [SMPTE RA]). Its use in the private_command() structure *shall* scope and identify only the private information contained within this command. This 32-bit number is used to identify the owner of the command.

@identifier [Optional; xsd:unsignedInt]

private_byte – The remainder of the descriptor is dedicated to data fields as required by the descriptor being defined.

PrivateBytes [Optional; xsd:hexBinary] If present, the PrivateBytes *shall* contain the hex binary representation of the private data.

Private means for communicating detailed vendor-unique ancillary information *should* be the only use of such data, and it *shall not* provide the same result as a standardized command.

9.8. Time

9.8.1. splice time()

The splice time() structure, when modified by pts adjustment, specifies the time of the splice event.

Table 13 - splice_time()

| Syntax | Bits | Mnemonic |
|--------------------------------|------|----------|
| splice_time() { | | |
| time_specified_flag | 1 | bslbf |
| if(time_specified_flag == 1) { | | |
| reserved | 6 | bslbf |
| pts_time | 33 | uimsbf |
| } | | |
| else | | |
| reserved | 7 | bslbf |
| } | | |

The XML schema for splice time() is shown in Figure 12.

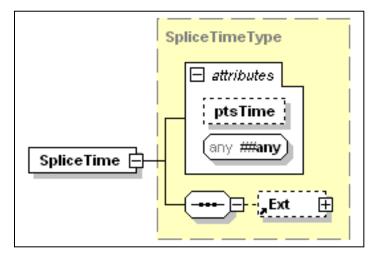

Figure 12 - SpliceTime

9.8.1.1. Semantic definition of fields in splice time()

time_specified_flag – A 1-bit flag that, when set to '1', indicates the presence of the pts_time field and associated reserved bits.

There is no entry in the XML schema for time_specified_flag. The value of time_specified_flag *shall* be set to '1' when converting an XML representation of the splice_insert to Bit Stream Format if the the ptsTime attribute is present in the SpliceTime Element; otherwise, the value of time_specified_flag *shall* be set to '0'.

pts_time – A 33-bit field that indicates time in terms of ticks of the program's 90 kHz clock. This field, when modified by pts_adjustment, represents the time of the intended splice point.

@ptsTime [Optional; PTSType] See section 13.2 for a description of PTSType.

9.8.2. break duration()

The break_duration() structure specifies the duration of the commercial break(s). It *may* be used to give the splicer an indication of when the break will be over and when the network In Point will occur.

Table 14 - break_duration()

| Syntax | Bits | Mnemonic |
|--------------------|------|----------|
| break_duration() { | | |
| auto_return | 1 | bslbf |
| reserved | 6 | bslbf |
| duration | 33 | uimsbf |
| } | | |

The XML schema for break duration() is shown in Figure 13

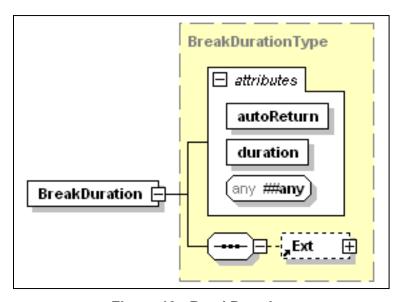

Figure 13 - BreakDuration

9.8.2.1. Semantic definition of fields in break duration()

auto_return – A 1-bit flag that, when set to '1', denotes that the duration **shall** be used by the splicing device to know when the return to the network feed (end of break) is to take place. A splice_insert() command with out_of_network_indicator set to 0 is not intended to be sent to end this break. When this flag is '0', the duration field, if present, is not required to end the break because a new splice_insert() command will be sent to end the break. In this case, the presence of the break_duration field acts as a safety mechanism in the event that a splice_insert() command is lost at the end of a break.

@autoReturn [Required; xsd:boolean]

duration – A 33-bit field that indicates elapsed time in terms of ticks of the program's 90 kHz clock.

@duration [Required; PTSType] See Section 13.2 for a description of PTSType.

9.9. Constraints

9.9.1. Constraints on splice info section()

The splice_info_section *shall* be carried in one or more PID stream(s) that are specific to a program and referred to in the PMT. The splice_info_section PID(s) *shall* be identified in the PMT by stream_type equal to 0x86.

The splice_info_section carried in one or more PID stream(s) referenced in a program's PMT *shall* contain only information about splice events that occur in that program.

A splice event *shall* be defined by a single value of splice event id.

If the Component Splice Mode will be used, then each elementary PID stream *shall* be identified by a stream_identifier_descriptor carried in the PMT loop, one for each PID. The stream_identifier_descriptor *shall* carry a component_tag, which uniquely corresponds to one PID stream among those contained within a program and listed in the PMT for that program.

Any splice_event_id that is sent in a splice_info_section using a splice_schedule() command *shall* be sent again prior to the event using a splice_insert() command. Hence, there *shall* be a correspondence between the splice_event_id values chosen for particular events signaled by the splice_schedule() command (distant future) and splice_event_id values utilized in the splice_insert() command (near future) to indicate the same events.

splice_event_id values do not need to be sent in an incrementing order in subsequent messages nor must they increment chronologically. splice_event_id values *may* be chosen at random. When utilizing the splice_schedule() command, splice_event_id values *shall* be unique over the period of the splice_schedule() command. A splice_event_id value *may* be re-used when its associated splice time has passed.

When the splice_immediate_flag is set to 1, the time to splice **shall** be interpreted as the current time. This is called the "Splice Immediate Mode". When this form is used with the splice_insert() command, the splice *may* occur at the nearest (prior or subsequent) opportunity that is detected by the splicer. The "Splice Immediate Mode" *may* be used for both splicing entry and exit points, i.e. for both states of out_of_network_indicator.

It *shall* be allowed that any avail *may* be ended with a Program Splice Mode message, a Component Splice Mode message or no message (whereby the break_duration is reached), regardless of the nature of the message at the beginning of the avail.

9.9.2. Constraints on the interpretation of time

9.9.2.1. Constraints on splice_time() for splice_insert()

For splice_command_type equal to 0x05 (splice_insert()), the following constraints on splice_time() *shall* apply:

At least one message for a network Out Point *shall* arrive at least 4 seconds in advance of the signaled splice time (pts_time as modified by pts_adjustment) if the time is specified. A Splice Immediate Mode message is allowed for a network Out Point, but the actual splice time is not defined and it is recommended that Splice Immediate Mode messages only be used for the early termination of breaks.

When non-Splice Immediate Mode cue messages are used for network In Points, the cue message *shall* arrive at the splicer before the arrival of the signaled In Point picture at the receiver.

An Out Point lies between two presentation units. The intended Out Point of a signaled splice event *shall* be the Out Point that is immediately prior to the presentation unit whose presentation time most closely matches the signaled pts time as modified by pts adjustment.

An In Point lies between two presentation units. The intended In Point of a signaled splice event *shall* be the In Point that is immediately prior to the presentation unit whose presentation time most closely matches the signaled pts time as modified by pts adjustment.

When the Component Splice Mode is in effect and the out_of_network_indicator is '1' (the beginning of a break), each component listed in the splice_insert() component loop *shall* be switched from the network component to the splicer supplied component at the time indicated. Components not listed in the component loop of the message will remain unchanged: if a splicer output component was the network component then it will remain the network component; if a splicer output component was the splicer supplied component then it will remain the splicer supplied component.

When the Component Splice Mode is in effect and the out_of_network_indicator is '0' (the end of a break), each component listed in the splice_insert() component loop *shall* be switched from the splicer supplied component to the network component at the time indicated. Components not listed in the component loop of the message will remain unchanged: if a splicer output component was the network component then it will remain the network component; if a splicer output component was the splicer supplied component then it will remain the splicer supplied component.

When the Component Splice Mode is in effect and the Splice Immediate Mode is not in effect, the first component listed in the component loop of the splice_insert() command *shall* have a valid pts_time in its associated splice_time() and this pts_time is referred to as the default pts_time. Subsequent components listed in the component loop of the same message, which don't have an associated pts_time, *shall* utilize this default pts_time. It *shall* be allowed that any and all components following the first listed component of a splice insert() command *may* contain a unique pts_time that is different from the default pts_time.

In the Component Splice Mode, all pts_time values given in the splice_insert component loop *shall* be modified by the pts_adjustment field to obtain each intended value for the signaled Out Point or In Point. The pts_adjustment, provided by any device that generates or modifies a pts_adjustment field value, *shall* apply to all pts_time fields in the message.

9.9.2.2. Constraints on break duration() for splice insert()

For splice_command_type equal to 0x05 (insert) the following constraints on break_duration() *shall* apply:

The value given in break_duration() is interpreted as the intended duration of the commercial break. It is an optional field to be used when the out_of_network_indicator equals 1. It *may* be used in the same splice_insert() command that specifies the start time of the break, so that the splicer can calculate the time when the break will be over.

Breaks may be terminated by issuing a splice_insert() command with out_of_network_indicator set to 0. A splice_time() may be given or the Splice Immediate Mode may be used. When a break_duration was given at the start of the break (where the auto_return was set to zero), the break_duration value may be utilized as a backup mechanism for insuring that a return to the network actually happens in the event of a lost cueing packet.

Breaks may also be terminated by giving a break duration at the beginning of a break and relying on the splicing device to return to the network feed at the proper time. The auto_return flag shall be 1. This will be referred to as the Auto Return Mode. Auto Return Mode breaks do not require and do not disallow cue messages at the end of the break with out_of_network_indicator set to 0. Hence, a receiving device should not expect a cue message at the end of a break in order to function properly. Auto Return Mode breaks may however be terminated early. To end the break prematurely, a second splice_insert() command may be given, where the out_of_network_indicator equals 0. The new time of the back to network splice may be given by an updated splice_time(), or the Splice Immediate Mode message may be used. A cue message with out_of_network_indicator set to 0 shall always override the duration field of a previous cue message (with out_of_network_indicator set to 1) if that break's signaled duration is still under way.

10. Splice Descriptors

10.1. Overview

The splice_descriptor is a prototype for adding new fields to the splice_info_section. All descriptors included use the same syntax for the first six bytes. In order to allow private information to be added, the 'identifier' code is available. This removes the need for a registration descriptor in the descriptor loop.

Any receiving equipment *should* skip any descriptors with unknown identifiers or unknown descriptor tags. For descriptors with known identifiers, the receiving equipment *should* skip descriptors with an unknown splice descriptor tag.

Splice descriptors may exist in the splice_info_section for extensions specific to the various commands.

Table 15 lists the defined Splice Descriptor Tags. Both the tag values that *shall* be used for Bit Stream Format as well as the XML Element that *shall* be used to identify each specific Splice Descriptor are listed.

Implementers note: Multiple descriptors of the same or different types in a single command are allowed and *may* be common. One case of multiple segmentation_descriptors is described in Section 10.3.3.2. The only limit on the number of descriptors is the section_length in Table 5, although there *may* be other practical or implementation limits.

| Tag | XML Element | Descriptors for Identifier "CUEI" |
|-------------|------------------------|---|
| 0x00 | AvailDescriptor | avail_descriptor |
| 0x01 | DTMFDescriptor | DTMF_descriptor |
| 0x02 | SegmentationDescriptor | segmentation_descriptor |
| 0x03 | TimeDescriptor | time_descriptor |
| 0x04 | AudioDescriptor | audio_descriptor |
| 0x05 - 0xFF | | Reserved for future SCTE splice_descriptors |

Table 15 - Splice Descriptor Tags

10.2. Splice descriptor

The Splice Descriptor syntax provided in this section is to be used as a template for specific implementations of a descriptor intended for the splice_info_section. It *should* be noted that splice descriptors are only used within a splice_info_section. They are not to be used within MPEG syntax, such

as the PMT, or in the syntax of any other standard. This allows one to draw on the entire range of descriptor tags when defining new descriptors.

| Syntax | Bits | Mnemonic |
|--|------|----------|
| <pre>splice_descriptor() {</pre> | | |
| splice_descriptor_tag | 8 | uimsbf |
| descriptor_length | 8 | uimsbf |
| identifier | 32 | uimsbf |
| for(i=0; i <n; i++)="" td="" {<=""><td></td><td></td></n;> | | |
| private_byte | 8 | uimsbf |
| } | | |
| } | | |

Table 16 - splice_descriptor()

The XML schema base type for all Splice Descriptors is SpliceDescriptorType. The XML schema for the SpliceDescriptorType base type is shown in Figure 14. The optional extension element is the only element defined within the base type.

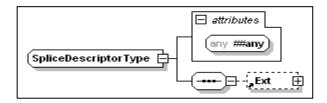

Figure 14 - SpliceDescriptorType

10.2.1. Semantic definition of fields in splice descriptor()

splice_descriptor_tag – This 8-bit number defines the syntax for the private bytes that make up the body of this descriptor. The descriptor tags are defined by the owner of the descriptor, as registered using the identifier.

There is no entry in the XML schema for splice_descriptor_tag. The value is implicit when transforming to or from an XML representation of the splice_descriptor() based on the specific descriptor Element supplied. The Element names can be found in the XML Element in Table 15.

descriptor_length – This 8-bit number gives the length, in bytes, of the descriptor following this field. Descriptors are limited to 256 bytes, so this value is limited to 254.

There is no entry in the XML schema for descriptor_length. The value *shall* be derived when converting an XML representation of the specific splice descriptor() to Bit Stream Format.

identifier – The identifier is a 32-bit field as defined in ISO/IEC 13818-1 [MPEG Systems], section 2.6.8 and 2.6.9, for the registration_descriptor() format_identifier. Only identifier values registered and recognized by SMPTE Registration Authority, LLC *should* be used (See [SMPTE RA]). Its use in this descriptor *shall* scope and identify only the private information contained within this descriptor. This 32-bit number is used to identify the owner of the descriptor. The code 0x43554549 (ASCII "CUEI") for descriptors defined in this specification has been registered with SMPTE.

There is no entry in the XML schema for identifier.

private_byte – The remainder of the descriptor is dedicated to data fields as required by the descriptor being defined.

There is no entry in the XML schema for private byte.

10.3. Specific splice descriptors

10.3.1. avail_descriptor()

The avail_descriptor is an implementation of a splice_descriptor. It provides an optional extension to the splice_insert() command that allows an authorization identifier to be sent for an avail. Multiple copies of this descriptor *may* be included by using the loop mechanism provided. This identifier is intended to replicate the functionality of the cue tone system used in analog systems for ad insertion. This descriptor is intended only for use with a splice insert() command, within a splice info section.

| Syntax | Bits | Mnemonic |
|-----------------------|------|----------|
| avail_descriptor() { | | |
| splice_descriptor_tag | 8 | uimsbf |
| descriptor_length | 8 | uimsbf |
| identifier | 32 | uimsbf |
| provider_avail_id | 32 | uimsbf |

Table 17 - avail_descriptor()

The XML schema for avail_descriptor() is shown in Figure 15.

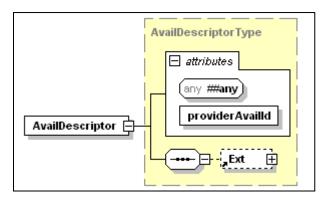

Figure 15 - AvailDescriptor

10.3.1.1. Semantic definition of fields in avail_descriptor()

splice_descriptor_tag – This 8-bit number defines the syntax for the private bytes that make up the body of this descriptor. The splice_descriptor_tag *shall* have a value of 0x00.

There is no entry in the XML schema for splice_descriptor_tag. The value is set to 0x00 when transforming from an XML representation of the avail descriptor() to Bit Stream Format.

descriptor_length – This 8-bit number gives the length, in bytes, of the descriptor following this field. The descriptor length field *shall* have a value of 0x08.

There is no entry in the XML schema for descriptor_length. The value *shall* be derived when converting an XML representation of the avail descriptor() to Bit Stream Format.

identifier – This 32-bit number is used to identify the owner of the descriptor. The identifier *shall* have a value of 0x43554549 (ASCII "CUEI").

There is no entry in the XML schema for identifier.

provider_avail_id – This 32-bit number provides information that a receiving device *may* utilize to alter its behavior during or outside of an avail. It *may* be used in a manner similar to analog cue tones. An example would be a network directing an affiliate or a head-end to black out a sporting event.

@providerAvailId [Required; xsd:unsignedInt]

10.3.2. DTMF descriptor()

The DTMF_descriptor() is an implementation of a splice_descriptor. It provides an optional extension to the splice_insert() command that allows a receiver device to generate a legacy analog DTMF sequence based on a splice_info_section being received.

| Syntax | Bits | Mnemonic |
|------------------------------------|------|----------|
| DTMF_descriptor() { | | |
| splice_descriptor_tag | 8 | uimsbf |
| descriptor_length | 8 | uimsbf |
| identifier | 32 | uimsbf |
| preroll | 8 | uimsbf |
| dtmf_count | 3 | uimsbf |
| reserved | 5 | bslbf |
| $for(i=0; i < dtmf_count; i++) $ { | | |
| DTMF_char | 8 | uimsbf |
| } | | |
| } | | |

Table 18 - DTMF_descriptor()

The XML schema for DTMF_descriptor() is shown in Figure 16.

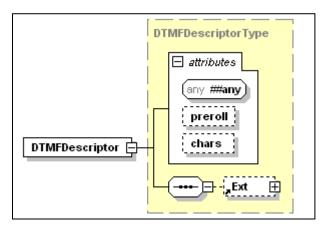

Figure 16 - DTMFDescriptor

10.3.2.1. Semantic definition of fields in DTMF descriptor()

splice_descriptor_tag – This 8-bit number defines the syntax for the private bytes that make up the body of this descriptor. The splice_descriptor_tag *shall* have a value of 0x01.

There is no entry in the XML schema for splice_descriptor_tag. The value is set to 0x01 when transforming from an XML representation of the DTMF_descriptor() to Bit Stream Format.

descriptor length – This 8-bit number gives the length, in bytes, of the descriptor following this field.

There is no entry in the XML schema for descriptor_length. The value *shall* be derived when converting an XML representation of the DTMF descriptor() to Bit Stream Format.

identifier – This 32-bit number is used to identify the owner of the descriptor. The identifier *shall* have a value of 0x43554549 (ASCII "CUEI").

There is no entry in the XML schema for identifier.

preroll – This 8-bit number is the time the DTMF is presented to the analog output of the device in tenths of seconds. This gives a pre-roll range of 0 to 25.5 seconds. The splice info section *shall* be sent at least two seconds earlier then this value. The minimum suggested pre-roll is 4.0 seconds.

@preroll [Optional; xsd:unsignedByte]

dtmf count – This value of this flag is the number of DTMF characters the device is to generate.

There is no entry in the XML schema for dtmf_count. The value *shall* be derived when converting an XML representation of the DTMF_descriptor() to Bit Stream Format based on the number of chars in @chars.

DTMF_char – This is an ASCII value for the numerals '0' to '9', '*', '#'. The device *shall* use these values to generate a DTMF sequence to be output on an analog output. The sequence *shall* complete with the last character sent being the timing mark for the pre-roll.

@chars [Optional; xsd:token]

10.3.3. segmentation_descriptor()

The segmentation_descriptor() is an implementation of a splice_descriptor(). It provides an optional extension to the time_signal() and splice_insert() commands that allows for segmentation messages to be sent in a time/video accurate method. This descriptor *shall* only be used with the time_signal(), splice_insert() and the splice_null() commands. The time_signal() or splice_insert() message *should* be sent at least once a minimum of 4 seconds in advance of the signaled splice_time() to permit the insertion device to place the splice_info_section() accurately.

Devices that do not recognize a value in any field *shall* ignore the message and take no action.

Table 19 - segmentation_descriptor()

| Syntax | Bits | Mnemonic |
|---|------|----------|
| segmentation descriptor() { | | |
| splice_descriptor_tag | 8 | uimsbf |
| descriptor_length | 8 | uimsbf |
| identifier | 32 | uimsbf |
| segmentation_event_id | 32 | uimsbf |
| segmentation_event_cancel_indicator | 1 | bslbf |
| reserved | 7 | bslbf |
| if(segmentation event cancel indicator == '0') { | | |
| program_segmentation_flag | 1 | bslbf |
| segmentation_duration_flag | 1 | bslbf |
| delivery_not_restricted_flag | 1 | bslbf |
| <pre>if(delivery_not_restricted_flag == '0') {</pre> | | |
| web_delivery_allowed_flag | 1 | bslbf |
| no_regional_blackout_flag | 1 | bslbf |
| archive_allowed_flag | 1 | bslbf |
| device_restrictions | 2 | bslbf |
| } else { | | |
| reserved | 5 | bslbf |
| } | | |
| if(program_segmentation_flag == '0') { | | |
| component_count | 8 | uimsbf |
| for(i=0;i <component_count;i++) th="" {<=""><td></td><td></td></component_count;i++)> | | |
| component_tag | 8 | uimsbf |
| reserved | 7 | bslbf |
| pts_offset | 33 | uimsbf |
| } | | |
| } :((| | |
| if(segmentation_duration_flag == '1') | 40 | |
| segmentation_duration | 40 | uimsbf |
| segmentation_upid_type | 8 8 | uimsbf |
| <pre>segmentation_upid_length segmentation upid()</pre> | 0 | uimsbf |
| segmentation_upid() segmentation type id | 8 | uimsbf |
| segment num | 8 | uimsbf |
| segments_expected | 8 | uimsbf |
| if(segmentation type id == '0X34' | 0 | uiiiioui |
| segmentation_type_id == '0X36') { | | |
| sub segment num | 8 | uimsbf |
| sub segments expected | 8 | uimsbf |
| } | | |
| } | | |
| , | | |

The XML schema representation of the Segmentation Descriptor is specified in Figure 17.

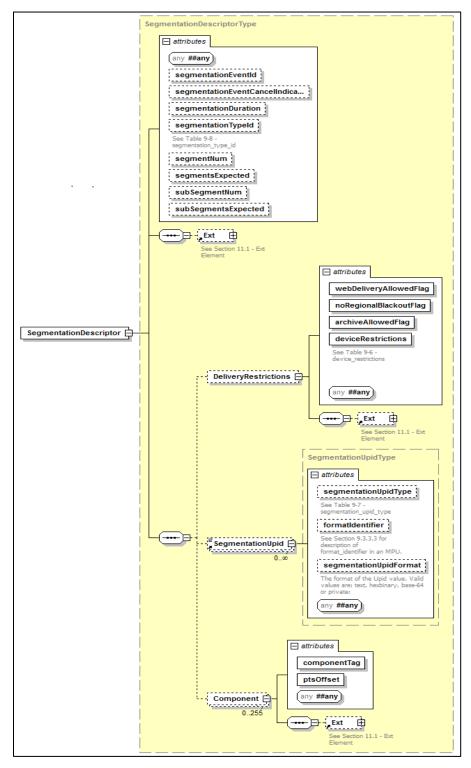

Figure 17 - SegmentationDescriptorType

10.3.3.1. Segmentation descriptor details

Semantic definition of fields in segmentation descriptor() as shown.

splice_descriptor_tag – This 8-bit number defines the syntax for the private bytes that make up the body of this descriptor. The splice descriptor tag *shall* have a value of 0x02.

There is no entry in the XML schema for splice_descriptor_tag. The value is set to 0x02 when transforming from an XML representation of the segmentation descriptor() to Bit Stream Format.

descriptor length – This 8-bit number gives the length, in bytes, of the descriptor following this field.

There is no entry in the XML schema for descriptor_length. The value *shall* be derived when converting an XML representation of the segmentation_descriptor() to Bit Stream Format.

identifier – This 32-bit number is used to identify the owner of the descriptor. The identifier *shall* have a value of 0x43554549 (ASCII "CUEI").

There is no entry in the XML schema for identifier.

segmentation_event_id – A 32-bit unique segmentation event identifier. Only one occurrence of a given segmentation_event_id value *shall* be active at any one time. See discussion in Section Segmenting Content - Additional semantics 10.3.3.5(below).

@segmentation event id [Optional; xsd:unsignedInt]

segmentation_event_cancel_indicator – A 1-bit flag that, when set to '1', indicates that a previously sent segmentation event, identified by segmentation_event_id, has been cancelled. The segmentation_type_id does not need to match between the original/cancelled segmentation event message and the message with the segmentation_event_cancel_indicator true. Once a segmentation event is cancelled, the segmentation_event_id *may* be reused for content identification or to start a new segment.

@segmentationEventCancelIndicator [Optional; xsd:Boolean] A value of TRUE *shall* be equivalent to a value of '1' and FALSE *shall* be equivalent to a value of '0'. If omitted, set segmentation event cancel indicator to 0 when generating a segmentation descriptor().

program_segmentation_flag – A 1-bit flag that *should* be set to '1' indicating that the message refers to a Program Segmentation Point and that the mode is the Program Segmentation Mode whereby all PIDs/components of the program are to be segmented. When set to '0', this field indicates that the mode is the Component Segmentation Mode whereby each component that is intended to be segmented will be listed separately by the syntax that follows. The program_segmentation_flag can be set to different states during different descriptors messages within a program.

There is no entry in the XML schema for program_segmentation_flag. The value of program_segmentation_flag *shall* be set to '1' when converting an XML representation of the segmentation_descriptor() to Bit Stream Format if there are no Component Elements present in the SegmentationDescriptor Element; otherwise, the value of program segmentation flag *shall* be set to '0'.

segmentation_duration_flag – A 1-bit flag that *should* be set to '1' indicating the presence of segmentation_duration field. The accuracy of the start time of this duration is constrained by the splice_command_type specified. For example, if a splice_null() command is specified, the precise position in the stream is not deterministic.

There is no entry in the XML schema for segmentation_duration_flag. The value of segmentation_duration_flag *shall* be set to '1' when converting an XML representation of the segmentation_descriptor() to Bit Stream Format if the segmentationDuration Attribute is specified; otherwise, the value of segmentation duration flag *shall* be set to '0'.

delivery_not_restricted_flag — When this bit has a value of '1', the next five bits are reserved. When this bit has the value of '0', the following additional information bits *shall* have the meanings defined below. This bit and the following five bits are provided to facilitate implementations that use methods that are out of scope of this standard to process and manage this segment.

There is no entry in the XML schema for delivery_not_restricted_flag. The value of delivery_not_restricted_flag *shall* be set to '0' when converting an XML representation of the segmentation_descriptor() to Bit Stream Format if the DeliveryRestrictions Element is specified; otherwise, the value of delivery not restricted flag *shall* be set to '1'.

web_delivery_allowed_flag – This bit *shall* have the value of '1' when there are no restrictions with respect to web delivery of this segment. This bit *shall* have the value of '0' to signal that restrictions related to web delivery of this segment are asserted.

@webDeliveryAllowedFlag [Conditional Mandatory; xsd:boolean] The webDeliveryAllowedFlag **shall** be specified if the DeliveryRestrictions Element is specified.

no_regional_blackout_flag – This bit *shall* have the value of '1' when there is no regional blackout of this segment. This bit *shall* have the value of '0' when this segment is restricted due to regional blackout rules.

@noRegionalBlackoutFlag [Conditional Mandatory; xsd:boolean] The noRegionalBlackoutFlag **shall** be specified if the DeliveryRestrictions Element is specified.

archive_allowed_flag – This bit *shall* have the value of '1' when there is no assertion about recording this segment. This bit *shall* have the value of 0 to signal that restrictions related to recording this segment are asserted.

@archiveAllowedFlag [Conditional Mandatory; xsd:boolean] The archiveAllowedFlag *shall* be specified if the DeliveryRestrictions Element is specified.

device_restrictions – See Table 20 for the meaning of this syntax element. This field signals three predefined groups of devices. The population of each group is independent and the groups are non-hierarchical. The delivery and format of the messaging to define the devices contained in the groups is out of the scope of this standard.

Table 20 - device_restrictions

| Segmentation Message | device_restrictions |
|----------------------|---------------------|
| Restrict Group 0 | 00 |
| Restrict Group 1 | 01 |
| Restrict Group 2 | 10 |
| None | 11 |

Restrict Group 0 – This segment is restricted for a class of devices defined by an out of band message that describes which devices are excluded.

Restrict Group 1 – This segment is restricted for a class of devices defined by an out of band message that describes which devices are excluded.

Restrict Group 2 – This segment is restricted for a class of devices defined by an out of band message that describes which devices are excluded.

None – This segment has no device restrictions.

@deviceRestrictions [Conditional Mandatory; xsd:unsignedByte] The deviceRestrictions *shall* be specified if the DeliveryRestrictions Element is specified.

component_count – An 8-bit unsigned integer that specifies the number of instances of elementary PID stream data in the loop that follows. Components are equivalent to elementary PID streams. If program_segmentation_flag == '0' then the value of component_count **shall** be greater than or equal to 1.

There is no entry in the XML schema for component_count. For Component Splice Mode, the value *shall* be derived when converting an XML representation of the segmentation_descriptor() to Bit Stream Format. component_count *shall* be set to the count of Component Elements supplied within the SegmentationDescriptor Element in the XML document.

component_tag – An 8-bit value that identifies the elementary PID stream containing the Segmentation Point specified by the value of splice_time() that follows. The value *shall* be the same as the value used in the stream_identifier_descriptor() to identify that elementary PID stream. The presence of this field from the component loop denotes the presence of this component of the asset.

@componentTag [Required, xsd:unsignedByte]

pts_offset – A 33-bit unsigned integer that **shall** be used by a splicing device as an offset to be added to the pts_time, as modified by pts_adjustment, in the time_signal() message to obtain the intended splice time(s). When this field has a zero value, then the pts_time field(s) **shall** be used without an offset. If splice_time() time_specified_flag = 0 or if the command this descriptor is carried with does not have a splice_time() field, this field **shall** be used to offset the derived immediate splice time.

@ptsOffset [Required, PTSType] See Section 13.2.

segmentation_duration – A 40-bit unsigned integer that specifies the duration of the segment in terms of ticks of the program's 90 kHz clock. It *may* be used to give the splicer an indication of when the segment will be over and when the next segmentation message will occur. **Shall** be 0 for end messages.

@segmentationDuration [Optional; xsd:unsignedLong]

segmentation_upid_type – A value from the following table. There are multiple types allowed to ensure that programmers will be able to use an id that their systems support. It is expected that the consumers of these ids will have an out-of-band method of collecting other data related to these numbers and therefore they do not need to be of identical types. These ids *may* be in other descriptors in the program and, where the same identifier is used (ISAN for example), it *shall* match between programs.

Table 21 - segmentation_upid_type

| segmentation_ upid_type | segmentati on_upid_le ngth (Bytes) | segmentation _upid() (Name) | Description | Example Textual Representation |
|----------------------------|---|-----------------------------------|--|---|
| 0x00 | 0 | Not Used | The segmentation_upid is not defined and is not present in the descriptor. | |
| 0x01 | variable | User Defined | Deprecated: use type 0x0C; The segmentation_upid does not follow a standard naming scheme. | User Defined |
| 0x02 | 8 | ISCI | Deprecated: use type 0x03, 8 characters; 4 alpha characters followed by 4 numbers. | ABCD1234 |
| 0x03 | 12 | Ad-ID | Defined by the Advertising Digital Identification, LLC group. 12 characters; 4 alpha characters (company identification prefix) followed by 8 alphanumeric characters. (See [Ad-ID]) | ABCD0001000H [SMPTE 2092-1] |
| 0x04 | 32 | UMID | See [SMPTE 330] | 060A2B34.010101 05.01010D20.1300 0000.D2C9036C.8 F195343.AB7014 D2.D718BFDA |
| 0x05 | 8 | ISAN | Deprecated: use type 0x06, ISO 15706 binary encoding. | n/a |
| 0x06 | 12 | ISAN | Formerly known as V-ISAN. ISO 15706-2 binary encoding ("versioned" ISAN). See [ISO 15706-2]. | 0000-0001-2C52- 0000-P-0000- 0000-0 |
| 0x07 | 12 | TID | Tribune Media Systems Program identifier. 12 characters; 2 alpha characters followed by 10 numbers. | MV0004146400 |
| 0x08 | 8 | TI | AiringID (Formerly Turner ID), used to indicate a specific airing of a program that is unique within a network. | 0x0A42235B81BC 70FC (expressed as hexadecimal) |
| 0x09 | variable | ADI | CableLabs metadata identifier as defined in Section 10.3.3.2. | provider.com/MO VE123456789012 3456 |

| segmentation_ upid_type | segmentati on_upid_le ngth (Bytes) | segmentation _upid() (Name) | Description | Example Textual Representation | |
|----------------------------|---|-----------------------------------|--|---|--|
| 0x0A | 12 | EIDR | An EIDR (see [EIDR]) represented in Compact Binary encoding as defined in Section 2.1.1 in EIDR ID Format (see [EIDR ID FORMAT]) | Content: 10.5240/0E4F- 892E-442F-6BD4- 15B0-1 Video Service: 10.5239/C370- DCA5 [SMPTE 2079] | |
| 0x0B | variable | ATSC Content Identifier | ATSC_content_identifier() structure as defined in [ATSC A/57B]. | Not Defined | |
| 0x0C | variable | MPU() | Managed Private UPID structure as defined in section 10.3.3.3. | User Defined | |
| 0x0D | variable | MID() | Multiple UPID types structure as defined in section 10.3.3.4. | See referenced UPID types | |
| 0x0E | variable | ADS Information | Advertising information. The specific usage is out of scope of this standard. | User Defined | |
| 0x0F | variable | URI | Universal Resource Identifier (see [RFC 3986]). | urn:uuid:f81d4fae- 7dec-11d0-a765- 00a0c91e6bf6 | |
| 0x10-0xFF | variable | Reserved | Reserved for future standardization. | | |

segmentation_upid_length – Length in bytes of segmentation_upid() as indicated by Table 21. If there is no segmentation upid() present, segmentation upid length *shall* be set to zero.

There is no entry in the XML schema for segmentation_upid_length. The value *shall* be derived when converting an XML representation of the SegmentationUpid to Bit Stream Format. In the case of UPID type MID(), this reflects the total length of nested UPID types structure. See Section 10.3.3.4. If there are no SegmentationUpid elements in an XML representation, segmentation_upid_length *shall* be set to zero in the Bit Stream Format.

segmentation_upid() – Length and identification from Table 21 - segmentation_upid_type. This structure's contents and length are determined by the segmentation_upid_type and segmentation_upid_length fields. An example would be a type of 0x06 for ISAN and a length of 12 bytes. This field would then contain the ISAN identifier for the content to which this descriptor refers.

SegmentationUpid [Optional, xsd:SegmenationUpidType] Zero, one or more SegmentationUpid Elements *may* be specified. If multiple SegmentationUpid Elements are present in an XML representation, the MID() structure *shall* be generated per Section 10.3.3.4. See Section 10.3.3.10 for additional details on SegmentationUpidType.

segmentation_type_id – The 8-bit value *shall* contain one of the values in Table 22 to designate type of segmentation. All unused values are reserved. When the segmentation_type_id is 0x01 (Content Identification), the value of segmentation_upid_type *shall* be non-zero. If segmentation_upid_length is zero, then segmentation type id *shall* be set to 0x00 for Not Indicated.

Table 22 - segmentation_type_id

| Segmentation Message | Segmentation_type_id | segment_num | segments_expected | sub_segment_num | sub_segments_expected |
|---------------------------------------|----------------------|---------------|-------------------|-----------------|-----------------------|
| | Hex (Decimal) | | | | |
| Not Indicated | 0x00 (00) | 0 | 0 | Not used | Not Used |
| Content Identification | 0x01 (01) | 0 | 0 | Not used | Not Used |
| Program Start | 0x10 (16) | 1 | 1 | Not used | Not Used |
| Program End | 0x11 (17) | 1 | 1 | Not used | Not Used |
| Program Early Termination | 0x12 (18) | 1 | 1 | Not used | Not Used |
| Program Breakaway | 0x13 (19) | 1 | 1 | Not used | Not Used |
| Program Resumption | 0x14 (20) | 1 | 1 | Not used | Not Used |
| Program Runover Planned | 0x15 (21) | 1 | 1 | Not used | Not Used |
| Program Runover Unplanned | 0x16 (22) | 1 | 1 | Not used | Not Used |
| Program Overlap Start | 0x17 (23) | 1 | 1 | Not used | Not Used |
| Program Blackout Override | 0x18 (24) | 0 | 0 | Not used | Not Used |
| Program Start – In Progress | 0x19 (25) | 1 | 1 | Not used | Not used |
| Chapter Start | 0x20 (32) | Non-zero | Non-zero | Not used | Not Used |
| Chapter End | 0x21 (33) | Non-zero | Non-zero | Not used | Not Used |
| Break Start | 0x22 (34) | 0 or Non-zero | 0 or Non-zero | Not used | Not used |
| Break End | 0x23 (35) | 0 or Non-zero | 0 or Non-zero | Not used | Not used |
| Opening Credit Start | 0x24 (36) | 1 | 1 | Not used | Not used |
| Opening Credit End | 0x25 (37) | 1 | 1 | Not used | Not used |
| Closing Credit Start | 0x26 (38) | 1 | 1 | Not used | Not used |
| Closing Credit End | 0x27 (39) | 1 | 1 | Not used | Not used |
| Provider Advertisement Start | 0x30 (48) | 0 or Non-zero | 0 or Non-zero | Not used | Not Used |
| Provider Advertisement End | 0x31 (49) | 0 or Non-zero | 0 or Non-zero | Not used | Not Used |
| Distributor Advertisement Start | 0x32 (50) | 0 or Non-zero | 0 or Non-zero | Not used | Not Used |

| Segmentation Message | Segmentation_type_id | segment_num | segments_expected | sub_segment_num | sub_segments_expected |
|---|----------------------|---------------|-------------------|-----------------|-----------------------|
| Distributor Advertisement End | 0x33 (51) | 0 or Non-zero | 0 or Non-zero | Not used | Not Used |
| Provider Placement Opportunity Start | 0x34 (52) | 0 or Non-zero | 0 or Non-zero | 0 or Non-zero | 0 or Non-zero |
| Provider Placement Opportunity End | 0x35 (53) | 0 or Non-zero | 0 or Non-zero | Not used | Not Used |
| Distributor Placement Opportunity Start | 0x36 (54) | 0 or Non-zero | 0 or Non-zero | 0 or Non-zero | 0 or Non-zero |
| Distributor Placement Opportunity End | 0x37 (55) | 0 or Non-zero | 0 or Non-zero | Not used | Not Used |
| Provider Overlay Placement Opportunity Start | 0x38 (56) | 0 or Non-zero | 0 or Non-zero | 0 or Non-zero | 0 or Non-zero |
| Provider Overlay Placement Opportunity End | 0x39 (57) | 0 or Non-zero | 0 or Non-zero | Not used | Not Used |
| Distributor Overlay Placement Opportunity Start | 0x3A (58) | 0 or Non-zero | 0 or Non-zero | 0 or Non-zero | 0 or Non-zero |
| Distributor Overlay Placement Opportunity End | 0x3B (59) | 0 or Non-zero | 0 or Non-zero | Not used | Not Used |
| Unscheduled Event Start | 0x40 (64) | 0 | 0 | Not used | Not Used |
| Unscheduled Event End | 0x41 (65) | 0 | 0 | Not used | Not Used |
| Network Start | 0x50 (80) | 0 | 0 | Not used | Not Used |
| Network End | 0x51 (81) | 0 | 0 | Not used | Not Used |

Notes:

- Only one Program Overlap Start is allowed to be active at a time. A Program End *shall* occur before a subsequent Program Overlap Start can occur.

 See [SCTE 223] for further usage of segmentation_type_id. 1.
- 2.

segment_num – This field provides support for numbering segments within a given collection of segments (such as chapters, advertisements or placement opportunities). This value, when utilized, is expected to reset to one at the beginning of a collection of segments. This field is expected to increment for each new segment (such as a chapter). The value of this field **shall** be as indicated in Table 22.

@segmentNum [Optional, xsd:unsignedByte]

segments_expected – This field provides a count of the expected number of individual segments (such as chapters) within a collection of segments. The value of this field *shall* be as indicated in Table 22.

@segmentsExpected [Optional, xsd:unsignedByte]

sub_segment_num – If specified, this field provides identification for a specific sub-segment within a collection of sub-segments. This value, when utilized, is expected to be set to one for the first sub-segment within a collection of sub-segments. This field is expected to increment by one for each new sub-segment within a given collection. If present, descriptor_length shall include sub_segment_num in the byte count and serve as an indication to an implementation that sub_segment_num is present in the descriptor.

The value of this field *shall* be as indicated in Table 22. Any other usage of sub_segment_num beyond that defined in Table 22 is out of scope of this standard.

If sub segment num is provided, sub segments expected *shall* be provided.

@subSegmentNum [Optional, xsd:unsignedByte]

sub_segments_expected — If specified, this field provides a count of the expected number of individual sub-segments within the collection of sub-segments. If present, descriptor_length *shall* include sub_segments_expected in the byte count and serve as an indication to an implementation that sub_segments_expected is present in the descriptor.

The value of this field *shall* be as indicated in Table 22. Any other usage of sub_segments_expected beyond that defined in Table 22 is out of scope of this standard.

@subSegmentsExpected [Optional, xsd:unsignedByte]

10.3.3.2. Cablelabs metadata identifier

When the value of segmentation_upid_type is 0x09 (ADI), it *shall* have the abbreviated syntax of <element> : <identifier>. The variable <element> *shall* take only the values "PREVIEW", "MPEG2HD", "MPEG2SD", "AVCHD", "AVCSD", "HEVCSD", "HEVCHD", "SIGNAL", "PO" (PlacementOpportunity), "BLACKOUT" and "OTHER".

SCTE 236² provides compatibility with this identifier model as described in [SCTE 236] Section 7.11.1. For SCTE 236 the variable <identifier> *shall* be a URI conforming to [RFC 3986].

² Formerly CableLabs Content 3.0

Any specifics on the systems that will ingest and process this information are out of scope of this standard.

10.3.3.3. MPU() definition and semantics

Table 23 - MPU()

| Syntax | Bits | Mnemonic |
|-------------------|------|----------|
| MPU() { | | |
| format_identifier | 32 | uimsbf |
| private_data | N*8 | uimsbf |
| } | | |

format_identifier – A 32-bit unique identifier as defined in ISO/IEC 13818-1 and registered with the SMPTE Registration Authority (See [SMPTE RA]).

private_data – A variable length, byte-aligned, set of data as defined by the registered owner of the format_identifier field value. The length is defined by the segmentation_upid_length, which includes the format_identifier field length.

10.3.3.4. MID() definition and semantics

Table 24 - MID()

| Syntax | Bits | Mnemonic |
|---|------|----------|
| MID() { | | |
| for (i=0; i <n; i++)="" th="" {<=""><th></th><th></th></n;> | | |
| segmentation_upid_type | 8 | uimsbf |
| length | 8 | uimsbf |
| segmentation_upid | N*8 | uimsbf |
| } | | |
| } | | |

segmentation upid type – As defined above.

length – segmentation upid length for the following segmentation upid.

segmentation_upid – segmentation_upid according to segmentation_upid_type as defined in Table 21.

Note: The number of segmentation_upid's present ("N") is not explicitly signaled. It is discovered by repeatedly parsing the fields above until segmentation upid length is exhausted.

There is no structure in the XML schema for MID(). When converting an XML document to Bit Stream Format, the presence of two or more SegmentationUpid Elements *shall* result in a MID() structure being inserted into the bit stream.

10.3.3.5. Segmenting Content - Additional semantics

One use of this descriptor is to signal content Segments. Segments are expected to have a logical hierarchy consisting of programs (highest level), chapters, placement opportunities, and advertisements (refer to Table 22). Provider and Distributor advertisements share the lowest logical level and *should not* overlap.

For the purposes of defining the semantics stated in this document section, the following definition applies:

Segment – shall be one of the segmentation_type_id values from Table 22, listed below. Occurrences of the segmentation_descriptor() that support Segments typically occur in pairs. The valid pairings are:

- Program Start/End Program End can be overridden by Program Early Termination
- Program Overlap Start/Program End
- Program Start In Progress/ Program End Program End can be overridden by Program Early Termination
- Program Breakaway/Resumption
- Chapter Start/End
- Break Start/End
- Opening Credit Start/End
- Closing Credit Start/End
- Provider Advertisement Start/End
- Distributor Advertisement Start/End
- Provider Placement Opportunity Start/End
- Distributor Placement Opportunity Start/End
- Provider Overlay Placement Opportunity Start/End
- Distributor Overlay Placement Opportunity Start/End
- Unscheduled Event Start/End
- Network Start/End

The following segmentation types (from Table 22) also support Segments but are not paired:

- Program Runover Planned
- Program Runover Unplanned

The following segmentation_types (from Table 22) are outside of the scope of this document section. They are not considered to support Segments (Segmenting Content):

- Not Indicated
- Content Identification

Descriptors *should* normally be paired, once for a given Segment start and then for Segment end. Each Segment end usage *may* be followed by another Segment start of the same logical level Segment. Refer to Section 10.3.3.6 (Programs), Section 10.3.3.7 (Chapters) and Section 10.3.3.11 (Placement Opportunities) for additional semantics. When a Segment's duration is provided, and that duration expires without a Segment end being signaled, then the value of segmentation_event_id *may* be reused if appropriate. Such inferred Segment end cases are not to be encouraged and *should not* be used.

In order to associate different types of segmentation constructs (such as associating Program level constructs with Chapter level constructs) the same segmentation_upid() *may* be used in the associated constructs. This however is not required.

The semantics of the fields within the segmentation_descriptor() for segmenting content are as follows (subject to additional constraints in other sections):

segmentation_event_id — When a Segment start is signaled, the segmentation_event_id value becomes active. While active, this value *shall not* be used to identify other segmentation events. When a Segment end is signaled, the segmentation event id value *shall* match the segment start segmentation event id

value and this value then becomes inactive and hence able to be used again for a new segmentation descriptor() occurrence including non-Segment usage such as Content Identification.

program segmentation flag – shall be set to '1'.

segmentation_duration_flag – If set to '1', a valid segmentation_duration *shall* be included in the descriptor. If segmentation type id is set to 0x10 (Program Start) then this flag *may* be set to '0'.

segment_num – *Shall* be set to non-zero values for Chapters ranging from one to the value of segments_expected on the Chapter Start. For Program segments, this value *shall* be set to one on the Program Start or Program Start – In Progress. This field *may* be optionally utilized for Advertisements in the same manner as Chapters.

segments_expected – *Shall* be set to a non-zero value on Chapter Start, Provider Advertisement Start, or Distributor Advertisement Start providing the number of starts in the program. For Program segments, this value *shall* be set to one.

sub_segment_num and **sub_segments_expected** *shall* only be specified on Placement Opportunity Start segments. See Section 10.3.3.11 for constraints specific to Placement Opportunity Start.

10.3.3.6. Programs - Additional semantics

When signaled, a Program *shall* begin with a segmentation_descriptor() containing a segmentation_type_id value of 0x10 (Program Start). The Program *shall* utilize a single and unique value for segmentation_event_id in all descriptors that pertain to this Program. The usage of a segmentation_upid() is optional but, if used, its value *shall* be uniquely assigned to this Program and not shared by Programs that are embedded within this Program. A Program *shall* end with a segmentation_descriptor() containing a segmentation_type_id value of 0x11 (Program End) or 0x12 (Program Early Termination).

The following segmentation messages *shall* only occur between the Program Start and Program End or Program Early Termination: Program Breakaway (segmentation_type_id value of 0x13); Program Resumption (segmentation_type_id value of 0x14); Program Runover Planned (segmentation_type_id value of 0x15); or Program Runover Unplanned (segmentation_type_id value of 0x16). A Program Resumption *shall* be preceded by a Program Breakaway. A program *may* be ended while in a Program Breakaway state.

Following a Program Breakaway, another Program Start to Program End sequence *may* occur, with new values of segmentation_event_id and segmentation_upid(). An entire embedded Program or Segments of an embedded Program *shall* be situated only between a Program Breakaway and a Program Resumption. Multiple instances of embedded Programs *may* occur. Note: Program Runover messages are asynchronous notifications and *may* occur at any time between the start and end of the program including within another embedded active program.

A Program Blackout Override (segmentation_type_id value of 0x18) *may* be sent between a Program Start or Program Start – In Progress and Program End or Program Early Termination. When a Program Blackout Override is received, the Delivery Restrictions from the Program Blackout Override message *may* be applied to the referenced Program (see section 10.3.3.9 "Delivery Restrictions – Additional Semantics").

If provided, the segmentation_duration *shall* be considered from the splice_time() of the time_signal command, if time is present, otherwise from the time the message is received. The duration clock

continues to increment during Program Breakaways. segmentation_duration can be extended using a Runover Planned or Runover Unplanned message. The value supplied in the new message is an update to the overall duration of the program and represents the elapsed time from the effective moment of the new message to the end of the segment. It is not an addition of elapsed time. If segmentation_duration is specified, when the duration is exceeded the program *shall* be considered terminated.

If at Program Start a duration is not provided, a duration *may* be provided at a later time using a Program Runover Planned or Program Runover Unplanned message.

If a duration is in effect, either set at Program Start or later introduced, segmentation_duration *may* be set to zero by sending a Program Runover Planned or Program Runover Unplanned message with segmentation_duration_flag set to '0'.

A Content Identification (value of segmentation_type_id 0x01) message with a value of segmentation_upid() matching the currently active Program *may* be sent on a periodic basis to make an implementation more robust. If sent, it *shall* match the values of segmentation_event_id and segmentation upid() used in the Program related messages.

This does not restrict Content Identification messages being sent that do not match the segmentation_event_id and segmentation_upid() used in the Program related messages. Other Content Identification messages can be inserted for other purposes.

10.3.3.7. Chapters - Additional semantics

A chapter Segment *shall* be introduced by a Chapter Start and ended by a Chapter End. For Chapter End, the value of segmentation_event_id *shall* match the value of segmentation_event_id for Chapter Start. If present, the segmentation_upid() *shall* be the same in both occurrences of a segmentation_descriptor() pair.

Chapter Segments *may* be associated with Program Segments using the same segmentation_upid() on both Chapter and Program messages.

Chapters *may* overlap. Chapters can be numbered using segment_num. The value of segments_expected on the Chapter Start *shall* indicate the expected number of chapters. Use of non-zero values for segmentation_duration on Chapter Start is optional.

10.3.3.8. Break - Additional semantics

Break numbering via Break Starts *shall* be supported per the following. The numbering of Breaks via Break Start messages are dependent on what is sent by a Provider in the Transport Stream:

- a) Program Segmentation descriptors are present in the Transport Stream and Break numbering within a Program is not supported.
- b) Program Segmentation descriptors are present in the Transport Stream and Break numbering within a Program is supported.
- c) Program Segmentation descriptors are not present in the Transport Stream and Break numbering within a Program is not supported.
- d) Program Segmentation descriptors are not present in the Transport Stream and Break numbering within a Program is supported.

If Program Segmentation descriptors (See Section 10.3.3.6) are present in the Transport Stream and Break numbering within a Program is not supported, Break Starts within the Program *shall* comply with the following:

- segments expected in all Break Starts *shall* be set to 0 (zero).
- segment num in all Break Starts *shall* be set to 0 (zero).

If Program Segmentation descriptors (See Section 10.3.3.6) are present in the Transport Stream and Break numbering within a Program is supported, Break Starts *shall* comply with the following:

- segments_expected in all Break Starts in a collection of Breaks within a Program *shall* be set to the expected number of Breaks within the Program.
- segment_num on the first Break Start *shall* be set to 1 (one) for the first Break and incremented by 1 for each subsequent Break within the Program.

10.3.3.9. Delivery Restrictions – Additional semantics

Delivery restrictions on the following segmentation types *shall* be applied in the absence of out of band data as described later in this section.

- Program Start
- Program Resumption
- Program Runover Planned
- Program Runover Unplanned
- Program Overlap Start
- Program Blackout Override
- Program Start In Progress
- Chapter Start
- Break Start
- Provider Advertisement Start
- Distributor Advertisement Start
- Provider Placement Opportunity Start
- Distributor Placement Opportunity Start
- Unscheduled Event Start
- Network Start

Delivery restrictions in end messages shall be ignored.

For Programs, a Program Blackout Override *shall* be used to provide new values for the delivery restrictions for the associated Program Start, Program Start – In Progress or Program Overlap Start message. See Section 10.3.3.6 for additional information.

For Programs, a Program Resumption *may* include new values for the delivery restrictions for the associated Program Start, Program Start – In Progress, or Program Overlap Start message.

The delivery restrictions from the most recent message *shall* be applied.

In addition to delivery restrictions in the SCTE 35 message, out of band data *may* be supplied (see [SCTE 224]). If there is matching out of band data, the matching out of band data that applies to the given program, advertising or unscheduled event *should* supersede the delivery flags and device restrictions from the SCTE 35 message.

10.3.3.10. Content Identifiers – Additional semantics

The following constraints *shall* be applied when including content identifiers in Segmentation Descriptors.

Programs *should* be identified using both video service and tv/movie EIDRs [EIDRA] (segmentation upid type=0x0A).

As an alternative to EIDR, an airing identifier that is globally unique to a given video service *may* be supplied (segmentation_upid_type=0x08). If known, the video service and tv/movie EIDRs [EIDR] *should* be supplied via some out of band mechanism. Alternate identifiers in an [SCTE 224] message is a mechanism that *may* be leveraged.

Advertisements *should* be identified using Distributor Advertisement Start or Provider Advertisement Start. The identifier *should* be an Ad-ID [Ad-ID] (segmentation upid type=0x03).

10.3.3.11. Placement Opportunities – Additional semantics

The additional semantics and constraints in this section shall apply to Placement Opportunity paired messages listed in Table 22 namely, Provider Placement Opportunity, Distributor Placement Opportunity, Provider Overlay Placement Opportunity and Distributor Overlay Placement Opportunity.

A Placement Opportunity *shall* be introduced by a corresponding Start message (for example, Provider Placement Opportunity Start) and closed by an associated End message (for example, Provider Placement Opportunity End). In the scenario where one Placement Opportunity is followed by another, the Placement Opportunity End segmentation message from one and Placement Opportunity Start segmentation in the next *may* reference the same PTS.

The Placement Opportunity Start segmentation types and associated Placement Opportunity End segmentation types *shall* have the same segmentation_event_id. See section 10.3.3.5 for additional constraints on segmentation_event_id.

Placement Opportunity Identifiers

Each Placement Opportunity Start and Placement Opportunity End *shall* be uniquely identifiable by one of two methods:

Method one utilizes a unique signal identifier. For this method the following *shall* be utilized:

- segmentation upid type set to 0x09
- segmentation upid set to "SIGNAL: <Base64 encoded GUID>"

Method two utilizes a unique airing id and break position. For this method the following shall be utilized:

- segmentation upid type set to 0x08
- segmentation upid set to a unique airing identifier
- The Distributor system infers the break position within the program based on order of receipt.

With either of the above two methods, the Placement Opportunity Start and End *may* also include an additional unique identity for a Placement Opportunity. In this case, the following *shall* be utilized:

- segmentation upid type set to 0x09
- segmentation upid set to "PO:<Base64 encoded GUID>"

If Placement Opportunity identifiers are present, associated Placement Opportunity Start and End *shall* carry the same Placement Opportunity identifiers. A given Placement Opportunity identifier *shall* appear in one Placement Opportunity Start and one Placement Opportunity End.

See [RFC 4648] for additional information on base-64 encoding. See Section 10.3.3.2 for additional information.

Placement Opportunity Break Numbering

Break numbering via Placement Opportunity Starts *shall* be supported per the following. The numbering of Breaks via Placement Opportunity Start messages are dependent on what is sent by a Provider in the Transport Stream sent to a Distributor:

- a) Program Segmentation descriptors are present in the Transport Stream and Break numbering within a Program is not supported.
- b) Program Segmentation descriptors are present in the Transport Stream and Break numbering within a Program is supported.
- c) Program Segmentation descriptors are not present in the Transport Stream and Break numbering within a Program is not supported.
- d) Program Segmentation descriptors are not present in the Transport Stream and Break numbering within a Program is supported.

If Program Segmentation descriptors (See Section 10.3.3.6) are present in the Transport Stream and Break numbering within a Program is not supported, Placement Opportunity Starts within the Program *shall* comply with the following:

- segments_expected in all Placement Opportunity Starts *shall* be set to 0 (zero).
- segment num in all Placement Opportunity Starts *shall* be set to 0 (zero).

If Program Segmentation descriptors (See Section 10.3.3.6) are present in the Transport Stream and Break numbering within a Program is supported, Placement Opportunity Starts *shall* comply with the following:

- segments_expected in all Placement Opportunity Starts in a collection of Placement Opportunities within a Program *shall* be set to the expected number of Breaks within the Program.
- segment_num on the first Placement Opportunity Start *shall* be set to 1 (one) for the first Break and incremented by 1 for each subsequent Break within the Program.

If Program Segmentation descriptors are not present in the Transport Stream and Break numbering within a Program is not supported, all Placement Opportunity Starts *shall* comply with the following:

- segments expected *shall* be set to 0 (zero)
- segment num *shall* be set to 0 (zero).

If Program segmentation descriptors are not present in the Transport Stream and Break numbering is supported, Placement Opportunity Starts *shall* comply with the following:

- segments_expected in all Placement Opportunity Starts in a group of Placement Opportunities *shall* be set to the expected number of Breaks in the next group of Breaks.
- segment_num on the first Placement Opportunity Start *shall* be set to 1 (one) for the first Break and incremented by 1 for each subsequent Break within the group of Breaks.

If the number of Breaks within the group of Breaks changes, increase or decrease, within the group, segments_expected on the next Placement Opportunity Start *shall* be updated with the new segments_expected. If number of Breaks within the group of Breaks is reduced after the last set of Placement Opportunity Starts are sent for a Break, the distributor implementation *should* recognize that no additional Breaks will be signaled when the next Placement Opportunity Start with segment_num equal to 1 is received. Since there are no Program related segmentation descriptors, the implementation *should* recognize when segment num is reset to one to indicate when a new group of Breaks is started.

A Break *may* have one or more Placement Opportunities. All Placement Opportunity Starts in a given break *shall* have the same values for segment_num and segments_expected. If the number of Breaks changes, increase or decrease, within the Program, segments_expected on the next Placement Opportunity Start *shall* be updated with the new segments_expected. If the number of Breaks is reduced after the last set of Placement Opportunity Starts are sent for a Break, the distributor implementation *should* recognize that no additional Breaks exist for a Program when the Program End message is received. A Placement Opportunity *shall* have one or more Placement Opportunity Ends. A Placement Opportunity *may* contain one or more nested Placement Opportunities. The Placement Opportunity Start and associated Placement Opportunity Ends for a contained Placement Opportunity *shall* be within the Placement Opportunity Start and first Placement Opportunity End of the containing Placement Opportunity.

The numbering of Placement Opportunities within a Break is dependent on whether:

- a) Placement Opportunity numbering within a Break is not supported
- b) Placement Opportunity numbering within a Break is supported

If Placement Opportunities within a Break are not numbered the Placement Opportunity Start *shall* comply with one of the following:

- sub_segment_num and sub_segments_expected may be omitted

OR

- sub segments expected *shall* be set to 0 (zero)
- sub segment num on all Placement Opportunity Starts *shall* be set to 0 (zero)
- both sub_segment_num and sub_segments *shall* be present in the segmentation descriptor and included in the overall byte count for the segmentation descriptor

If Placement Opportunities within a Break are numbered and contains only one opportunity the Placement Opportunity Start *should* comply with the following:

- sub segments expected *shall* be set to 1 (one)
- sub_segment_num on the first Placement Opportunity Start shall be set to 1 (one)

If the number of Placement Opportunities within a Break increases from 1 (one) after the first Placement Opportunity Start for the break is sent, sub_segments_expected on the next Placement Opportunity Start *shall* be updated with the new segments_expected.

If Placement Opportunities within a Break are numbered and there are multiple Placement Opportunity Starts within a break, the Placement Opportunity Starts *shall* comply with the following:

- sub_segments_expected *shall* be set to the expected number of Placement Opportunity Start messages expected within the break.

- sub_segment_num on the first Placement Opportunity Start *shall* be set to 1 (one) and incremented by one on each subsequent Placement Opportunity Start.

If the number of Placement Opportunities change, increase or decrease, within the Break, sub_segments_expected on the next Placement Opportunity Start *shall* be updated with the new sub_segments_expected. If the number of Placement Opportunities is reduced after the last Placement Opportunity Start is sent for a Break, the distributor implementation *should* recognize that no additional Breaks will be signaled when the next Placement Opportunity Start with sub_segment_num equal to 1 (one) is received.

Multiple Placement Opportunity End Messages

Additional Placement Opportunity End segmentation types that have the same segmentation_event_id as the Placement Opportunity Start *may* be present. To inform downstream systems of the number of Placement Opportunity End segmentation types to be expected in the PID stream associated with a given Placement Opportunity Start, the segmentation descriptor *shall* comply with the following:

- segmentation_duration on the Placement Opportunity Start *shall* be the duration defined by the last Placement Opportunity End.
- segmentation_event_id *shall* have the same value on all Placement Opportunity End segmentation types as the associated Placement Opportunity Start.
- segments_expected on all Placement Opportunity End segmentation types *shall* be set to the number of Placement Opportunity End segmentation types to be sent.
- segment_num on the first Placement Opportunity End *shall* be set to 1 (one) and incremented by one on each subsequent Placement Opportunity End.
- segmentation_upid on the Placement Opportunity Start or Placement Opportunity End *may* include one Placement Opportunity identifier or, if more than one Placement Opportunity identifier, Placement Opportunity identifiers in a MID() structure.

If the number of Placement Opportunity Ends change, increase or decrease, within the Placement Opportunity, sub_segments_expected on the next Placement Opportunity End *shall* be updated with the new sub_segments_expected. If the number of Placement Opportunity Ends is reduced after the last Placement Opportunity End is sent for a Placement Opportunity, the distributor implementation *should* recognize that no additional Placement Opportunity Ends will be signaled when the next Placement Opportunity message with a new segmentation_event_id is received.

The segmentation_duration on the Placement Opportunity Start *shall* be the duration of the underlying content for the Break. If multiple Placement Opportunity End segmentation types are associated with a Placement Opportunity Start, the segmentation_duration in the Placement Opportunity Start *should* be the duration defined by the last Placement Opportunity End sharing the same segmentation_event_id. If a Placement Opportunity End with a sub_segment_num equal to expected Placement Opportunity Ends is received prior to reaching the duration in the Placement Opportunity Start, the Placement Opportunity *shall* be considered closed.

In those cases where a Provider chooses to provide supplemental information to a Distributor, the information may be passed in a segmentation_upid using a segmentation_upid_type of ADS Information (0x0E). An out of band mechanism may also be leveraged to provide supplemental information about a Placement Opportunity (See [SCTE 224]).

10.3.4. time_descriptor()

The time_descriptor is an implementation of a splice_descriptor. It provides an optional extension to the splice_insert(), splice_null() and time_signal() commands that allows a programmer's wall clock time to be sent to a client. For the highest accuracy, this descriptor *should* be used with a time_signal() or splice_insert() command that has the time_specified_flag equal to 1. This command *may* be inserted using SCTE 104 or by out of band provisioning on the device inserting this message.

The repetition rate of this descriptor *should* be at least once every 5 seconds. When it is the only descriptor present in the time_signal() or splice_null() command, then the encoder *should not* insert a key frame.

This command *may* be used to synchronize time based external metadata with video and the party responsible for the metadata and the time value used *should* insure that they are properly synchronized and have the desired level of accuracy required for their application.

10.3.4.1. Informative description of TAI

The time_descriptor() uses the time format defined for the Precision Time Protocol [PTP]. [PTP] is based upon an international time scale called International Atomic Time (TAI), unlike NTP [RFC5905] which is based upon UTC. [PTP] is being used in a/v bridging and broadcast synchronization protocols and likely to be available in a studio environment. Other time sources, such as NTP or GPS, are readily convertible to PTP format.

TAI does not have "leap" seconds like UTC. When UTC was introduced (January 1, 1972) it was determined there *should* be a difference of 10 seconds between the two time scales. Since then an additional 27 leap seconds (including one in December 2016) have been added to UTC to put the current difference between the two timescales at 37 seconds (as of June 2018) The [PTP] protocol communicates the current offset between TAI and UTC to enable conversion. By default [PTP] uses the same "epoch" (i.e. origination or reference start time and date of the timescale) as Unix time, of 00:00, January 1, 1970. Readers are advised to consult IERS Bulletin C for the current value of leap seconds [https://www.iers.org/IERS/EN/Publications/Bulletins/bulletins.html].

Table 25 - time_descriptor()

| Syntax | Bits | Mnemonic |
|-----------------------|------|----------|
| time_descriptor() { | | |
| splice_descriptor_tag | 8 | uimsbf |
| descriptor_length | 8 | uimsbf |
| identifier | 32 | uimsbf |
| TAI_seconds | 48 | uimsbf |
| TAI_ns | 32 | uimsbf |
| UTC_offset | 16 | uimsbf |
| } | | |

The XML schema for the time descriptor() is shown in Figure 18.

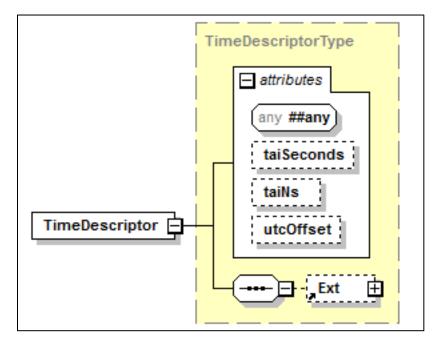

Figure 18 - TimeDescriptor

10.3.4.2. Semantic definition of fields in time_descriptor()

splice_descriptor_tag – This 8-bit number defines the syntax for the private bytes that make up the body of this descriptor. The splice descriptor tag *shall* have a value of 0x03.

There is no entry in the XML schema for splice_descriptor_tag. The value is set to 0x03 when transforming from an XML representation of the time descriptor() to Bit Stream Format.

descriptor_length – This 8-bit number gives the length, in bytes, of the descriptor following this field. The descriptor_length field *shall* have a value of 0x10.

There is no entry in the XML schema for descriptor_length. The value *shall* be derived when converting an XML representation of the time descriptor() to Bit Stream Format.

identifier – This 32-bit number is used to identify the owner of the descriptor. The identifier *shall* have a value of 0x43554549 (ASCII "CUEI").

There is no entry in the XML schema for identifier.

TAI_seconds – This 48-bit number is the TAI seconds value.

@taiSeconds [Optional; xsd:unsignedLong with a restriction up to 48 bits (281474976710656).

TAI_ns – This 32-bit number is the TAI nanoseconds value.

@taiNs [Optional; xsd:unsignedInt]

UTC_offset – This 16-bit number *shall* be used in the conversion from TAI time to UTC or NTP time per the following equations.

UTC seconds = TAI seconds - UTC offset

NTP seconds = TAI seconds - UTC offset +2,208,988,800

@utcOffset [Optional; xsd:unsignedShort]

10.3.4.1. Synchronized Client Clock

The time_descriptor() provides a mechanism to associate a programmer's wall clock time with a presentation time in the media timeline as specified by the PTS carried in the splice_time structure of the command. The time_descriptor() *may* be used by a downstream device, such as a packager or set-top, to determine the offset to its local time-of-day clock with the incoming stream.

Figure 19 illustrates how the time-of-day SMPTE time code associated with a frame would be converted to TAI and associated with a presentation time stamp (PTS) value. The receiving equipment could then know the studio/origination time of any frame in the system by knowing the PTS to TAI offset. So, if the system inserts a time_descriptor every 5 seconds randomly and it happens to insert one on the second frame in the figure, a relationship is established with the PTS time of 711500 to a TAI of 14:12:38.0166. Now if a packager wants to insert an ID3 tag or cause a segment break and wants to name a file on the 08:12:01:21 SMPTE frame, it can take the current PTS of 740000 and subtract the 711500 value to get a 28500 difference in 90 kHz clock ticks and know that the wall clock time that has significance to the programmer was at 14:12:38.333 TAI.

Date August 28 2018, LeapSeconds=37, frame rate=60

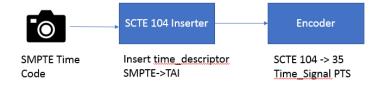

Figure 19 - Time Relationships

If stream processing results in a change in the time base, the splice_time, if present, **shall** either be rewritten or the pts_adjustment field **shall** carry the offset necessary to adjust the PTS carried in splice time to the new time base so that the time descriptor() maintains its accuracy.

If the value of a time_descriptor is carried into DASH or HLS media segments, the PTS value carried in splice_time, if present, *shall* be converted to the corresponding media time base and be carried as appropriate to the target format, for example an 'emsg' (or 'prft') structure in a DASH ISOBMFF media

segment or an ID3 tag in an HLS media segment.

As the packets containing the time_descriptor() may not align with segment boundaries or other specific points in the delivery format, it may be necessary to derive new presentation and wall clock times from the time_descriptor() if that alignment is required. The packager or other stream processor is responsible for adjusting the presentation time and programmer's wall clock time carried in the time_descriptor() appropriately.

An example would be to use this derived wall clock time to place a timestamp at the beginning of each media segment. One could use this timestamp, carried as a tag in the manifest file or in the media segments, to synchronize with external metadata.

10.3.4.2. Synchronized Clock carriage in HLS Timed Metadata (ID3 tags)

HLS defines a mechanism for carrying timed metadata as ID3 frames carried in PES packets, with associated PTS values. [HLS-TMD]

Two existing ID3 frames may be used to carry the contents of a time_descriptor, TDRL (release time) or TDEN (encoding time). Both of these carry a UTC timestamp in ISO 8601 format as described in the ID3v2 structure document [ID3v2-strct]. These timestamps provide a precision of seconds.

If finer precision is required the timestamp may be carried in an SCTE-defined private (PRIV) ID3 tag.

The format for PRIV frames per [ID3v2-strct] is:

Header <"PRIV">

The owner identifier *shall* be <standards@scte.org>

The private data *shall* be <scte35-time\$00time> where "time" is an ISO 8601 timestamp with ms accuracy.

10.3.5. audio descriptor()

The audio_descriptor() *should* be used when programmers and/or MVPDs do not support dynamic signaling (e.g., signaling of audio language changes) and with legacy audio formats that do not support dynamic signaling. As discussed in Section 9.1.5 of the SCTE Operational Practice on Multiple Audio Signaling [SCTE 248], since most MVPD headends do not change the PAT/PMT to signal changed audio streams, this descriptor in SCTE 35 should be used to signal such changes. This descriptor is an implementation of a splice_descriptor(). It provides the ability to dynamically signal the audios actually in use in the stream. This descriptor *shall* only be used with a time_signal command and a segmentation descriptor with the type Program Start or Program Overlap Start.

Table 26 - audio_descriptor()

| Syntax | Bits | Mnemonic |
|---|------|----------|
| audio_descriptor() { | | |
| splice_descriptor_tag | 8 | uimsbf |
| descriptor_length | 8 | uimsbf |
| identifier | 32 | uimsbf |
| audio_count | 4 | uimsbf |
| reserved | 4 | bslbf |
| for (i=0; i <audio_count; i++)="" th="" {<=""><th></th><th></th></audio_count;> | | |
| component_tag | 8 | uimsbf |
| ISO_code | 24 | uimsbf |
| Bit_Stream_Mode | 3 | uimsbf |
| Num_Channels | 4 | uimsbf |
| Full_Srvc_Audio | 1 | uimsbf |
| } | | |
|] } | | |

The XML schema for audio descriptor() is shown in Figure 20.

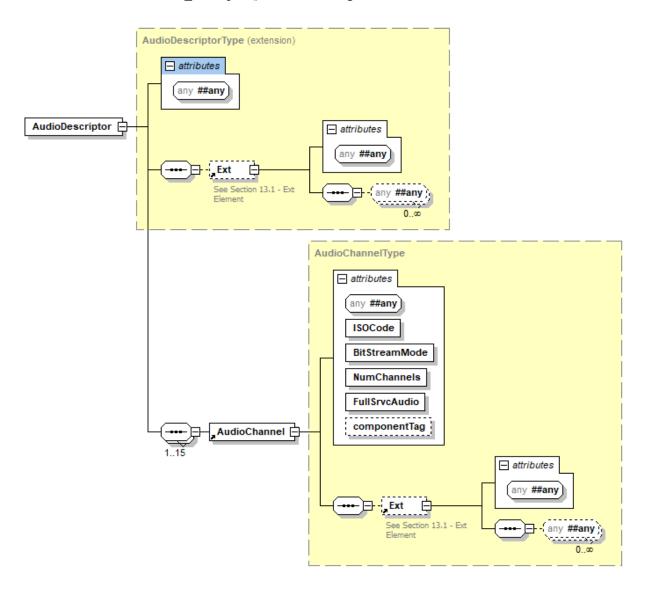

Figure 20 - AudioDescriptor

10.3.5.1. Semantic definition of fields in audio_descriptor()

splice_descriptor_tag – This 8-bit number defines the syntax for the private bytes that make up the body of this descriptor. The splice descriptor tag *shall* have a value of 0x04.

There is no entry in the XML schema for splice_descriptor_tag. The value is set to 0x04 when transforming from an XML representation of the audio_descriptor() to Bit Stream Format.

descriptor_length – This 8-bit number gives the length, in bytes, of the descriptor following this field.

There is no entry in the XML schema for descriptor_length. The value *shall* be derived when converting an XML representation of the audio descriptor() to Bit Stream Format.

identifier – This 32-bit number is used to identify the owner of the descriptor. The identifier *shall* have a value of 0x43554549 (ASCII "CUEI").

There is no entry in the XML schema for identifier.

audio count – The value of this flag is the number of audio PIDs in the program.

There is no entry in the XML schema for audio_count. The value *shall* be derived when converting an XML representation of the audio_descriptor() to Bit Stream Format based on the number of audio channels.

component_tag – An optional 8-bit value that identifies the elementary PID stream containing the audio channel that follows. If used, the value *shall* be the same as the value used in the stream_identifier_descriptor() to identify that elementary PID stream. If this is not used, the value *shall* be 0xFF and the stream order *shall* be inferred from the PMT audio order.

@componentTag [Required, xsd:unsignedByte]

ISO_code – This field is a 3-byte language code defining the language of this audio service which *shall* correspond to a registered language code contained in the Code column of the [ISO 639-2] registry.

@chars [Optional; xsd:language]

Bit Stream Mode – As per ATSC A/52 Table 5.7.

@chars [Required, xsd:unsignedByte]

Num_Channels – As per ATSC A/52 Table A4.5.

(a)chars [Required, xsd:unsignedByte]

Full Srvc Audio – (From ATSC A/52 Annex A.4.3)

"This is a 1-bit field that indicates if this audio service is a full service suitable for presentation, or a partial service which should be combined with another audio service before presentation. This bit *should* be set to a '1' if this audio service is sufficiently complete to be presented to the listener without being combined with another audio service (for example, a visually impaired service which contains all elements of the program; music, effects, dialogue, and the visual content descriptive narrative). This bit *should* be set to a '0' if the service is not sufficiently complete to be presented without being combined with another audio service (e.g., a visually impaired service which only contains a narrative description of the visual program content and which needs to be combined with another audio service which contains music, effects, and dialogue)."

@chars [Required, xsd:unsignedByte]

11. Encryption

11.1. Overview

The splice_info_section supports the encryption of a portion of the section in order that one *may* prevent access to an avail to all except those receivers that are authorized for that avail. This chapter of the document describes the various encryption algorithms that *may* be used. The encryption of the section is optional, as is the implementation of encryption by either the creator of the message, or any receive

devices. The use of encryption is deemed optional to allow a manufacturer to ship "in-the-clear" systems without worrying about the export of encryption technology. If encryption is included in the system, any receive device *shall* implement all of the algorithms listed in this document, which allows the creator of a splice info table to use any of the algorithms in a transmission. The use of private encryption technology is optional, and out of the scope of this document.

11.2. Fixed key encryption

The encryption used with this document assumes a fixed key is to be used. The same key is provided to both the transmitter and the receiver. The method of delivering the key to all parties is unspecified. This document allows for up to 256 different keys to be available for decryption. The cw_index field is used to determine which key *should* be used when decrypting a section. The length of the fixed key is dependent on the type of algorithm being used. It is assumed that fixed key delivered to all parties will be the correct length for the algorithm that is intended to be used.

11.3. Encryption algorithms

NOTE: FIPS Publication 46-3 was withdrawn on May 19, 2005 and implementers that require encryption of SCTE 35 messages *may* wish to use a user private encryption algorithm.

The encryption_algorithm field of the splice_info_section is a 6-bit value, which *may* contain one of the values shown in Table 27. All Data Encryption Standard variants use a 64-bit key (actually 56 bits plus a checksum) to encrypt or decrypt a block of 8 bytes. In the case of triple DES, there will need to be 3 64-bit keys, one for each of the three passes of the DES algorithm. The "standard" triple DES actually uses two keys, where the first and third keys are identical. See [FIPS PUB 46-3] and [FIPS PUB 81].

| Value | Encryption algorithm | |
|-------|----------------------------|--|
| 0 | No encryption | |
| 1 | DES – ECB mode | |
| 2 | DES – CBC mode | |
| 3 | Triple DES EDE3 – ECB mode | |
| 4-31 | Reserved | |
| 32-63 | User private | |

Table 27 - Encryption algorithm

11.3.1. DES - ECB mode

This algorithm uses the "Data Encryption Standard", (see [FIPS PUB 81]), in the electronic codebook mode.

In order to use this type of encryption, the encrypted data *shall* contain a multiple of 8 bytes of data, from splice_command_type through to E_CRC_32 fields. The alignment_stuffing loop *may* be used to pad any extra bytes that *may* be required.

11.3.2. DES - CBC mode

This algorithm uses the "Data Encryption Standard" (see [FIPS PUB 81]), in the cipher block chaining mode. The basic algorithm is identical to DES ECB. Each 64-bit plaintext block is bitwise exclusive-ORed with the previous ciphertext block before being encrypted with the DES key. The first block is exclusive-ORed with an initial vector. For the purposes of this document, the initial vector *shall* have a fixed value of zero.

In order to use this type of encryption, the encrypted data *shall* contain a multiple of 8 bytes of data, from splice_command_type through to E_CRC_32 fields. The alignment_stuffing loop *may* be used to pad any extra bytes that *may* be required.

11.3.3. Triple DES EDE3 – ECB mode

This algorithm uses three 64-bit keys, each key being used on one pass of the DES-ECB algorithm (see [FIPS PUB 46-3]). Every block of data at the transmit device is first encrypted with the first key, decrypted with the second key, and finally encrypted with the third key. Every block at the receive site is first decrypted with the third key, encrypted with the second key, and finally decrypted with the first key.

In order to use this type of encryption, the encrypted data *shall* contain a multiple of 8 bytes of data, from splice_command_type through to E_CRC_32 fields. The alignment_stuffing loop *may* be used to pad any extra bytes that *may* be required.

11.3.4. User private algorithms

This document allows for the use of private encryption algorithms. It is not specified how the transmit and receive devices agree on the algorithm to use for any user private code. It is also not specified as to how coordination of private values for the encryption_algorithm field *should* be registered or administered.

12. SCTE 35 Usage

12.1. SCTE 35 Usage in DASH

SCTE 35 messages can be carried in DASH. See [SCTE 214-1], [SCTE 214-2] and [SCTE 214-3].

12.2. SCTE 35 Usage in HLS

Manipulation of an HLS m3u8 manifest is used to provide seamless ad insertion. The manifest is modified to include targeted ads prior to delivery to the player or the manifest is modified at the player before delivery to the device's video playback engine. These mechanisms allow for seamless playback without buffering or other interruptions in the playback experience. HLS m3u8 manifest manipulation can be done on a server or on a client (for example, to implement companion ads). Client-side ad insertion typically would need a secure player implementation to insure the ad segments play out correctly.

This document presents two alternatives for SCTE 35 messages that are carried in HLS. The recommended approach is based on [HLS-TMD] and is clarified in section 12.2.1. The legacy approach is specified in section 12.2.2. Both methods can be used in the same manifest and it is up to the implementer to use the appropriate markings for the devices and players that they require compatibility with.

12.2.1. SCTE 35 markup in HLS using EXT-X-DATERANGE

Carriage of SCTE 35 in HLS using EXT-X-DATERANGE is described in [HLS-TMD].

For clarification, when using the END-ON-NEXT attribute, the CLASS attribute *should* be set to the segmentation_type_id value of the associated splice out cue. This ensures that sequential cues of the same time can be labeled by the same CLASS.

12.2.2. SCTE 35 markup in HLS using EXT-X-SCTE35

Ad cues and other signaling metadata are placed into the HLS m3u8 manifest file using HLS tags and attribute lists.

The SCTE 35 HLS tag definition in this standard is consistent with HLS tag definitions in [HLS].

The SCTE 35 HLS attributes on the tag definition in this standard is consistent with HLS attribute definition in [HLS].

The SCTE 35 HLS attributes *shall* comply with the following:

| Attribute Type | AttributeValue Data Type |
|----------------|--------------------------|
| Number | decimal-floating-point |
| String | quoted-string |

The general method of operation utilizes tags marking the beginning and end of each signaled sequence of content segments. In this way it is possible to signal placement opportunities, local (distributor) avails and provider advertisements.

Using tags marking the beginning and end of each signaled sequence of content segments *may* also be used to control stream blackouts using manifest manipulation on the server, so restricted content is never sent to the viewer.

12.2.3. HLS cue tags

The #EXT-X-SCTE35 is the only tag defined by this standard.

Table 28 - Tag #EXT-X-SCTE35

| Tag Name | Attributes | Description |
|---------------|------------|---|
| #EXT-X-SCTE35 | CUE | Tag representing an embedded SCT35 |
| | DURATION | message as a binary representation as |
| | ELAPSED | described in section 7.4 The binary |
| | ID | representation <i>shall</i> be encoded in Base64 as |
| | TIME | defined in section 7.4 of [RFC 4648] with |
| | TYPE | W3C recommendations. The client or manifest |
| | UPID | manipulator should decode the Base64 |
| | BLACKOUT | encoded string, then apply Table 5 to interpret |
| | CUE-OUT | the message. |
| | CUE-IN | |
| | SEGNE | |

Table 29 - Tag attributes

| Attribute Name | Attribute Type | Required | Description |
|----------------|----------------|----------|---|
| CUE | String | Required | The SCTE 35 binary message encoded in |
| | | | Base64 as defined in section 7.4 of [RFC] |
| | | | 4648] with W3C recommendations. |

| Attribute Name | Attribute Type | Required | Description |
|----------------|-----------------------|----------|--|
| DURATION | Double | Optional | The duration of the signaled sequence defined by the CUE. The duration is expressed in seconds to millisecond accuracy. |
| ELAPSED | Double | Optional | Offset from the CUE (typically a start segmentation type) of the earliest presentation time of the HLS media segment that follows. If an implementation removes fragments from the manifest file (e.g., live application), the ELAPSED value <i>shall</i> be adjusted by the duration of the media segments removed. Elapsed is expressed in seconds to millisecond accuracy. |
| ID | String | Optional | A unique value identifying the CUE. |
| TIME | Double | Optional | TIME represents the start time of the signaled sequence. If present in a stream, the SCTE 35 time descriptor <i>should</i> be utilized as the time basis. Since time descriptor uses TAI, a conversion to UTC is required, see section 10.3.4.2. TIME <i>shall</i> be the UTC time corresponding to the start time of the first inserted HLS media segment. TIME <i>shall</i> be to millisecond accuracy. To calculate the actual temporal position within the content for the CUE, add TIME and ELAPSED. |
| ТҮРЕ | Integer | Optional | If present, the segmentation_type_id from the SCTE 35 segmentation descriptor. (See Table 22, NOTE: An Integer <i>may</i> be expressed as a decimal or in other bases such as hexadecimal. When hex representation is used the value <i>should</i> be preceded by 0x) |
| UPID | String | Optional | Quoted string containing the segmentation_upid_type and the segmentation_upid separated by a colon. The segmentation_upid_type is an ascii hex value prefixed with 0x or 0X. The segmentation_upid is an ascii hex prefixed with 0x or 0X, or an ascii string representation of the decoded binary. If segmentation_upid_type is 0x0D (MID), seperate each <segmentation_upid_type:segmentation_upid>pair with a semi-colon.</segmentation_upid_type:segmentation_upid> |
| BLACKOUT | String | Optional | Enumeration of delivery restriction states as determined by business logic in the packager. Valid values are: YES, NO (default), MAYBE. YES indicates content is currently subject to blackout. MAYBE indicates content |

| Attribute Name | Attribute Type | Required | Description |
|----------------|----------------|----------|---|
| | | | is subject to conditional restrictions and that external authorization is required for rights enforcement (i.e., regional blackout and/or device restrictions). NO indicates content is not subject to restriction. |
| CUE-OUT | String | Optional | Signal to begin ad insertion. Valid values are: YES, NO (default), CONT. CONT signals the "continuation" of a break replacement opportunity started with CUE-OUT on a previous tag. Used for partial break replacement when a player joins mid-break. When CONT is present, the ELAPSED and DURATION attributes should be included. |
| CUE-IN | String | Optional | Signal to stop replacing content. Valid values are: YES, NO (default) |
| SEGNE | String | Optional | Values from the segment_num and segment_expected fields, expressed as decimal integers and delimited with a colon. For example, SEGNE="3:3" |

12.2.4. HLS playlist example

The following HLS example illustrates a possible live programming scenario that includes a full complement of #EXT-X-SCTE 35 tags.

- 1) Network Start (0x50) 2015-12-01T00:00:00+00:00 32400.0 seconds of elapsed video removed from the playlist since original tag at 1448928000.000
- 2) Program Start (0x10) 2015-12-01T09:00:00+00:00 Blackout attribute indicates a potential regional blackout.
- 3) Provider Placement Opportunity Start (0x34) Duration 60.060 seconds Cue-Out indicates dynamic ad insertion/replacement is desired by the publisher
 - a. Distributor Placement Opportunity Start (0x36)
 - b. Distributor Placement Opportunity End (0x37)
- 4) Provider Placement Opportunity End (0x35)
- 5) Program End (0x11) and Program Start (0x10) for the next program, which is not subject to blackout restrictions.

The SCTE35 Base64 CUE values have been omitted for the sake of space and clarity of the example.

13. SCTE 35 XML elements and types

In addition to the SCTE 35 XML types and associated elements and attributes described in earlier sections of this specification, this section provides details on additional SCTE 35 XML elements and types.

13.1. Ext element

The Ext (extensibility) element allows zero or more elements from any namespace to be included. This element facilitates expansion, customization, and extensibility of the specification. Encapsulating elements from external namespaces into a single element allows filters, transforms, and other operations to be applied easily. See Figure 21.

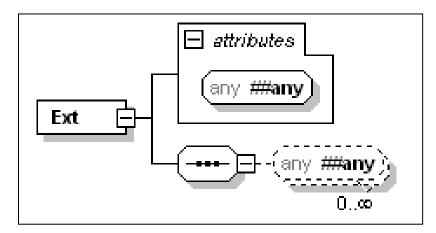

Figure 21 - Ext Element

@##any [Optional] – Any additional attribute from any namespace.

##any[Optional] – Zero or more elements from any namespace. (Zero elements are allowed as all the data *may* be included via attributes.)

13.2. PTSType

PTSType is a simple type used to specify a PTS Time. PTSType is an xsd:unsignedLong that can hold 33-bit time. It is constrained to a minimum value of 0 and a maximum value of 8589934592. The default value is 0.

13.3. Segmentation Upid Element

The Segmentation Upid Element is used to express a UPID in an XML document. See 10.3.3 segmentation descriptor() for usage in a segmentation descriptor.

The XML schema for SegmentationUpid is shown in Figure 22.

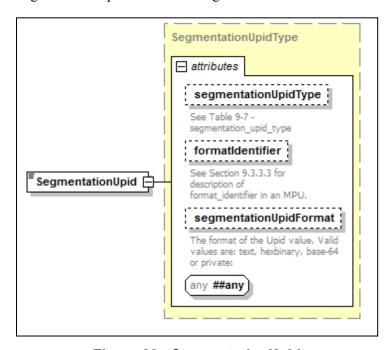

Figure 22 - SegmentationUpid

@segmentationUpidType [Optional, xsd:unsignedByte]. See Table 21 for valid values. The value for MID() *shall not* be specified. MID() *shall* be implied based on the presence of multiple SegmentationUpid Elements.

@formatIdentifier [Optional, xsd:unsignedInt]. Specify for MPU only. See section 10.3.3.3 for description of format_identifier in an MPU.

@segmentationUpidFormat. The format of the UPID value. Valid values are: text, hexBinary, base-64 or private.

14. Sample SCTE 35 Messages (Informative)

These are examples. In actual practice, there would be many variations of options and their use. These examples are meant to provide an overview and insight into the use and capabilities of Messages within this standard.

The decoding of the hex/base64 strings omits some redundant information such as the CUEI identifier for clarity. These examples are the output from the open source decoder available on github.

14.1. Time_Signal - Placement Opportunity Start

This is an example of using the Time_Signal command with a segmentation descriptor. The programmer that created this message used the Web Delivery Allowed flag to indicate the broadcast advertisements should be blacked out. This would tend to also indicate that digital ad insertion would be used to insert new advertisements in their place. The programmer is also using the segment number in a non-normative manner to indicate that there are distributor placement opportunities within this provider placement opportunity. A standardized method of doing this would be to use the MID format of the segmentation UPID type and insert a UPID type 0x0E (ADS) with this information.

Also note the Tier value in this message is 0xfff as displayed on the output of a receiver. It is likely that the value of Tier in transmission had a different value that this receiver was authorized to receive, and the receiver obfuscated that by changing the value to 0xfff.

2018-07-16 00:04:57 M274P29528596539

Hex=0xFC3034000000000000FFFF00506FE72BD0050001E021C435545494800008E7FCF0001A599B00808000000002CA0A18A3402009AC9D17E Base64=/DA0AAAAAAA///wBQb+cr0AUAAeAhxDVUVJSAAAjn/PAAGImbAlCAAAAAAAsoKGKNAIAmsnRfg==

14.2. Splice Insert

This is the legacy standard for a distributor placement opportunity. As a significant number of existing ad servers will not respond to the newer time signal command, it is likely that this message will be in use until the legacy components are removed and replaced. The programmer that generated this message uses the break duration and auto return mode for the splice insert. The break duration at 60.293567 seconds is slightly longer than the contracted 60 second local avail; it is, however, the exact duration of the content that the local avail will overlay. This means that the encoder will generate a key frame at that specified

break duration from the splice time and the affiliate should fill the duration with a slate or black (in some countries a blue color is used). Some splicers or fragmented file delivery systems may be able to adjust the duration and boundaries to match the key frames as well.

14.8. Time_Signal - Program Start/End - Placement Opportunity End

This is a complex message, although one that can occur frequently as many ad breaks are placed at the end of the program. The implementer should take care though to find the length and current practice is to try and keep the message in a single transport packet.
